P11.08: THE COMPARISON OF ENOS MUTATION 894G>T AND ITS RELATIONSHIP WITH ARTERIAL STIFFNESS

To link to this article: https://doi.org/10.1016/j.artres.2011.10.164

Published online: 14 December 2019
variables between both groups were determined with two-way ANOVA. Relationships between LV twist and AIx were identified using Pearson’s product moment correlation.

Results: Heart rate and blood pressure did not differ between the two groups at rest or during exercise (p>0.05). While LV twist and AIx were significantly related in both the moderate and high fitness group (r^2: 0.31 and 0.44, respectively, p<0.01), the high VO2 max group had a significantly lower LV twist for the same AIx (p<0.001, see figure).

Conclusions: In young healthy individuals, LV twist and AIx are significantly related. However, the lower LV twist in individuals with high aerobic fitness cannot be explained by AIx, heart rate or blood pressure and, therefore, may indicate a previously unknown component of LV adaptation related to aerobic fitness.

**24 HOUR AMBULATORY CENTRAL BP MEASUREMENT REVEALS SIGNIFICANT VARIATION IN PULSE PRESSURE AMPLIFICATION BETWEEN DAY AND NIGHT**

*University of Cambridge, Cambridge, United Kingdom*

Introduction: Brachial ambulatory blood pressure monitoring (ABPM) provides greater predictive value for cardiovascular events than clinic blood pressure (BP) readings. However, systolic BP varies throughout the arterial tree, such that brachial BP readings do not reliably indicate central (aortic) pressure. As yet, 24 hour ambulatory central BP, and central to peripheral pressure amplification have not been described.

Methods: 24 hour ambulatory brachial and central BP monitoring was undertaken in 122 healthy, treatment-naive individuals (71 females), using the mobilograph device (IEM, Germany). The mean age was 48±20 years (range 18-80 years). Ambulatory measurements were made every 30 minutes during the day and every 60 minutes overnight. Clinic (seated) BP was also assessed, prior to undertaking ambulatory measurements.

Results: Mean clinic (seated) BP was 130±21/79±11mmHg. During the daytime, mean ambulatory BP was 125±14/80±12mmHg (brachial) and 115±14/82±12mmHg (central). During the nighttime, both brachial (115±16/70±12mmHg) and central (107±15/71±11mmHg) ambulatory BP fell significantly (P<0.001 for all comparisons, Figure 1). However, the ratio between brachial and central pressures (pulse pressure amplification) was significantly higher during the daytime (1.38±0.15) compared with nighttime (1.23±0.11, P=0.002).

Conclusions: Monitoring of ambulatory central BP reveals significant variation in pulse pressure amplification over a 24 hour period. These data indicate that ambulatory central and brachial BP are differentially affected by the activities of daily living. Further studies are required to investigate whether the prognostic value of ambulatory central BP is superior to ambulatory brachial BP.

Background: Pulse wave velocity is a strong predictor of cardiovascular events and mortality. It is known that NO can influence arterial stiffness through vascular tone regulation. The presence of eNOS mutations can influence arterial stiffness. Purpose of the study was to investigate the relation between 894G>T mutation and arterial stiffness.

Material and method: The study included 70 subjects (63.4% women), in whom the 894G>T polymorphism (the PCR method) and arterial stiffness (using the TensioMedTMArteriograph) were determined. The mean age of the subjects was 59.8±11.01 years, without significant sex differences.

Results: The distribution depending on the presence of genotypes was for the 894G'T mutation as follows: 42.3% of the subjects were negative (GG), 40.8% heterozygous (GT) and 16.9% homozygous (TT). No significant differences were found between sexes (women vs men) regarding the presence of genotypes: GG 44.4% vs 38.5%, GT 44.4% vs 34.6%, TT 11.1% vs 26.9%, p=NS. Globally, there was no significant difference of the PWVAo values between homozygous and heterozygous or negative patients: 9.6±1.53m/ sec in TT patients vs 10.36±1.79m/sec in GT patients vs 10.10±1.98 m/sec in GG patients(p=NS). There were no significant differences between the values of Aixb, AixAo, PP according to GG vs GT vs TT genotype (generally or per sexes), but homozygous patients (TT) had higher Aixb, PP values, respectively.

Conclusions: In the present study, the presence of the TT homozygote state was not associated with the increase of PWVAo, but seems to determine Aixb and PP increases.

P11.09
SHEAR STRAIN IN THE COMMON CAROTID ARTERIAL WALL RELATED TO AGE?
T. Idzenga, S. Holewijn, H. H. G. Hansen, C. L. De Korte
Radboud University Nijmegen Medical Center, Nijmegen, Netherlands

The primary trigger for myocardial infarction and stroke is destabilization of atherosclerotic plaques. It has been hypothesized that locally increased longitudinal shear strain (LSS) facilitates the development of vulnerable plaques [1]. LSS is defined as the change of longitudinal deformation in radia
tional direction. Ultrasound strain imaging allows local assessment of LSS [2].

In 8 asymptomatic volunteers (age: 20–64 yrs.), radiofrequency (rf) ultrasound data of the common carotid artery were acquired in longitudinal direction using a Medison Accuvix V10, equipped with an LS-13 linear array transducer (f 0 = 8.5 MHz). In each volunteer rf data were acquired at three beam steering angles during multiple cardiac cycles [3]. Simultaneously the ECG-signal was recorded. LSS was estimated in a selected region-of-interest (ROI) using a coarse-to-fine cross correlation based algorithm [3,4].

The estimated shear strain showed a cyclic pattern with an increase during the systolic and a decrease during the diastolic phase. The maximum LSS ranged between 3 and 17% and appeared to decrease with age. This decrease could be related to stiffening of the arterial wall.

This study provides initial normal values of LSS in the common carotid artery. The maximum LSS appears to decrease with age. Further validation in patients will open the door for clinical predictions of plaque rupture.

PRESSURE-INDEPENDENT ASSOCIATION BETWEEN AORTIC STIFFNESS AND LEFT VENTRICULAR CONCENTRIC GEOMETRY
G. Schillaci, G. Pucci, L. Settimi, M. Pilati, A. Baroni, E. Mannarino
University of Perugia, Perugia, Italy

Background: Systolic blood pressure (BP) is the main pressure determinant of left ventricular (LV) mass in hypertension. It is uncertain whether arterial stiffness and central hemodynamics are related to LV mass and geometry independent of brachial, central or 24-hour BP level.

Methods: 744 consecutive never-treated subjects with uncomplicated hypertension (men 59%, age 49±11 years, BP 149/93±16/10 mmHg) underwent M-mode echocardiography and 24-hour BP monitoring. Carotid-femoral pulse wave velocity (cfPWV), aortic augmentation and aortic BP were evaluated by applanation tonometry.

Results: Women with LV hypertrophy (LV mass >51 g/m²²) had a higher cfPWV (10.5±3 vs 9.3±2 m/s, p=0.001), augmentation (21±7 vs 16±7 mmHg, p<0.001) and heart rate-corrected augmentation index (37±8 vs .34±12, p=0.04). Similar data were found in men. LV relative wall thickness (RWT) but not LV mass index was significantly associated with cfPWV independent of age and brachial, central or 24h systolic BP (see Table).

The association of aortic augmentation with LV mass and RWT was no longer significant after adjustment for age and systolic BP. In a multiple regression model, 24h systolic BP, LV mass and cfPWV (all p<0.05) independently predicted LV-RWT when a consistent number of risk factors was simultaneously controlled for.

Conclusion: The impact of aortic PWV on LV concentric geometry is independent and additional to that of peripheral, central or 24h BP.

2 Vilnius University, Vilnius, Lithuania

Objective: To identify the frequency and character of cardiovascular events in patients with systemic lupus erythematosus (SLE) and to examine the risk factors for their development.

Materials and methods. The database of SLE was looked through to determine the frequency of cardiovascular events among the patients with the following case control study being designed. Seventy two patients formed the case control study out of which 27 had a cardiovascular event in the past and 45 were controls without the event matching the control by disease duration.

Results. Since 2003 year 175 patients were diagnosed with SLE and treated at tertiary rheumatology center. Twenty seven out of them have experienced the cardiovascular events and some of them for several times. In total 37 cardiovascular events were diagnosed. Angina pectoris was the most common event. Patients with cardiovascular events were older at the time of the event, more likely to have higher platelet counts in the blood, lower hemoglobin and less disease activity index score compared to controls. Cases were also more likely to have taken higher doses of corticosteroids [17.8(11.5) vs 12.9(8.0)] and higher white blood cell count in the blood [7.5(4.5) vs 5.4(2.7)]. In multivariable logistic regression analyses, only leukocytosis was significant risk factor for the development of cardiovascular events. The other two factors: age and the use of higher steroid doses have drawn near but haven’t crossed the level of statistical significance. This research was funded by a grant (No. MIP – 83/2010) from the Research Council of Lithuania.

B2-MICROGLOBULIN, PULSE PRESSURE AND METABOLIC ALTERATIONS IN PATIENTS ON HEMODIALYSIS
V. Raikou 1, N. Tentolouris 1, D. Kyriaki 2, A. Evaggelatou 2, J. Boletis 3
1 1st Dpt of Medicine Propaedeutic, National and Kapodistrian University of Athens, General Hospital “Laiko”, Athens, Greece

3 Dpt of Nephrology and Transplantation, General Hospital “Laiko”, Athens, Greece

Background/Aim: Pulse pressure (PP) is a result of arterial stiffness seen in dialysis patients, but may be a consequence of fluid overload. We examined the role of beta2-microglobulin (ß(M) in PP in relation to metabolic alterations in patients on different hemodialysis (HD) modalities.

Methods: We studied 76 hemodialyzed patients on regular HD (n = 34), pre-
dilution bagged hemodiafiltration (n = 19) and online predilution hemodia-
filtration (n = 23). ß(M) levels were measured by radioimmunoassay, and the clearance of ß(M) was assessed by Kt/V for ß(M). Arterial stiffness was measured as carotid femoral pulse wave velocity, and PP was derived. Insulin levels were measured using immunoradiassay, and insulin resistance was calculated using homeostasis model assessment insulin resistance (HOMA-IR). Serum bicarbonate levels were measured using a blood gas analyzer, and percent sodium removal was calculated.

Results: ß(M) levels predict increased PP (p = 0.02) adjusting for age, HD modalities, HD duration, HOMA-IR and percent sodium removal. ß(M) was positively associated with HOMA-IR (r = 0.306, p = 0.007). Serum bicarbonate levels and carotid-femoral pulse wave velocity were inversely associated (r = −0.719, p = 0.001).

Conclusions: ß(M) levels were positively associated with PP, which was influ-
enced mainly by dialysis modality fluid and sodium balance and less by arte-
rial stiffness. ß(M) levels were positively associated with insulin resistance. Uremic acidosis may contribute to arterial stiffness.
