Published online: 21 December 2019
Results: Recruitment began in January 2008 and will be completed in June 2012. It is hypothesized that there will be no significant difference in LV mass between groups. However, there will be significantly reduced use of medication and improved quality of life in the central BP group because more appropriate titration choices will be made to maintain normal central SBP.

Conclusion: Principal findings will be presented at ARTERY 12.

Background: HIV infection is linked to higher cardiovascular risk. Adverse outcomes may be mediated through mechanisms of endothelial dysfunction attributed to nitric oxide (NO) inhibition. The aim of the study was to compare blood plasma levels of asymmetric dimethylarginine (ADMA), a natural NO inhibitor, of HIV infected patients who are either naive to treatment or on antiretroviral therapy (ART) and healthy controls.

Methods: 108 subjects were studied: 29 non-infected controls and 79 HIV infected patients [33 naive to treatment, 30 on a nucleoside reverse transcriptase inhibitor (NRTI/NNRTI) and 16 on a nucleoside reverse transcriptase inhibitor plus a protease inhibitor combination (NRTI/PI)]. Plasma ADMA levels were measured using a commercially available ELISA kit. Between group comparisons were made using non-parametric tests.

Results: HIV infected patients had higher ADMA levels compared to controls (P = 0.003). ADMA levels differed significantly across groups; non-infected controls had the lower levels of ADMA (P = 0.001). Among HIV infected patients, those on ART exhibited higher ADMA levels versus ART-naive patients [0.84 (0.77, 1.05) μmol/L for ART versus 0.67 (0.26, 0.86) μmol/L for ART-naive patients, P = 0.002]. ADMA levels did not differ between patients on NNRTIs [0.86 (0.77, 1.10) or Pls (0.82 (0.71, 0.95)], P = 0.31.

Conclusions: ART-naive patients exhibit lower ADMA levels, denoting increased NO bioavailability compared to patients on ART; this may be associated with their lower viral load that translates in a diminished inflammatory burden and better functional status. Patients on NNRTIs and Pls have comparable ADMA plasma levels.

The common carotid artery (CCA) is an unusual localization of fibromuscular dysplasia (FMD). However, we previously detected CCA phenotypic alterations in a small population of patients with renal FMD and validated a CCA score. We aimed to test this score in a larger population of patients with renal FMD and hypertension.

Methods: CCA score was calculated with a high resolution echotracking device as the sum of B-mode and radiofrequency score as follows: B-mode: Normal = 1; discontinuous blood-intima interface = 2; discontinuous additional interface within the media = 3; continuous interface within the media = 4. Radiofrequency signals: Constant normal two-waved (double) signal = 1; alternation of double and triple signal over successive acquisitions = 2; constant three-wave (triple) signal = 3.

Results: 185 hypertensive patients with renal FMD (40 patients with unifocal and 145 with multifocal lesions) and a control group of 79 hypertensive patients without renal FMD were enrolled. Prevalence of CCA score > 3 was higher in patients with multifocal, with or without string of beads, than unifocal FMD and controls (Figure 1). In multivariate analysis, intima-media thickness (150mm increase: OR 1.83, 95%CI 1.27-2.64; P = 0.001) and FMD distribution (renal FMD alone: OR 2.97, 95%CI 1.38-6.37; P = 0.01. Multisite FMD: OR 6.03; 95%CI 2.62-13.89; P = 0.001.) were associated with CCA score > 3.

Conclusions: Phenotypic alterations of the CCA were reported in subjects with renal FMD with a higher prevalence in those with multifocal lesions. The CCA score > 3 is associated with FMD distribution and intima-media thickness.

HIGH OUTPUT, LOW RESISTANCE HAEMODYNAMICS ARE ASSOCIATED WITH AUGMENTATION INDEX IN PATIENTS WITH TYPE 2 DIABETES

R. E. Climeie, S. Nikolic, L. J. Keith, J. E. Sharman
The Menzies Research Institute Tasmania, Hobart, Australia

Objectives: Augmentation index (Alx) is associated with increased arterial stiffness. However, several reports have shown that Alx is not significantly raised in patients with type 2 diabetes (T2DM) despite having increased arterial stiffness. This suggests different mechanisms contributing to Alx in T2DM, although the exact cause is unknown. The aim of this study was to examine haemodynamic determinates of Alx in healthy people compared with T2DM.

Methods: Resting haemodynamics were recorded in 53 T2DM patients (aged 61±8 years, 51% male) and 53 matched controls (aged 58±6, 51% male). Tonometry was used to record Alx, central blood pressure (BP) and aortic stiffness (aPWV). Cardiac output (CO) and systemic vascular resistance (SVR) were measured using impedance cardiography.

Results: There was no significant difference between groups in Alx (24±11 vs 27±9%, p = 0.107). T2DM patients had significantly higher aPWV (7.6±1.6 vs 6.8±1.9 m/s), heart rate (64.9 ± 9 vs 57.7± 7.0 bpm), CO (5.54±1.15 vs 4.49±0.71 L/min), and central SBP (114±11 vs 107±12 mmHg), but lower SVR (1326±249 vs 1559±281d. cm⁻³/min/(p<0.05 all). The strongest correlates of Alx in T2DM patients were heart rate (r = -0.632), CO (r = -0.604) and SVR (r = 0.542)(p< 0.001 all). However, these were not related to Alx in controls.

Objectives. Vascular mechanisms underlying brain atrophy and white matter lesions (WML) in patients with type 2 diabetes (T2DM) are unknown. Increased exercising blood pressure (BP) is associated with end-organ damage and could explain these brain abnormalities. This study examined associations between exercise central haemodynamics and brain structure.

Methods. Forty healthy participants (53±9 years; 50% male) and 40 T2DM (62±9 years; 50% male) were examined at rest and during light exercise. Resting and exercise central haemodynamics, including systolic BP (SBP), pulse pressure (PP) augmented pressure (AP), augmentation index (AIx), aortic stiffness and aortic reservoir function (including excess pulse integral [xPI]) were recorded by tonometry. Segmented grey (GM) and white matter (WM) volumes, and significant elevation of all central hemodynamic variables during exercise (<0.01 all). At rest, greater central (not brachial) haemodynamics (SBP, AP, Alx and PP) were independently associated with greater WM volume (β=0.54, p=0.003; β=0.55, p=0.01; β=0.46, p=0.046 and; β=0.48, p=0.01, respectively) in controls (not T2DM). During exercise, increased xPI was independently associated with reduced WM (β=0.54, p=0.10) volumes only in T2DM independent of age, sex, heart rate, and 24-hour ambulatory SBP.

Conclusions: In T2DM, aortic reservoir function and transmission of excess pressure during exercise is associated with brain atrophy. These findings suggest that vascular mechanisms underlying structural brain changes may differ between healthy individuals and those with T2DM.

An increased arterial stiffness (AS) has been proposed as a likely mechanism for a reduced cardiac baroreflex sensitivity (BRs) and the associated increases in 24h blood pressure (BP) variability. Aim of the present study was to explore this issue in a group of 90 normotensive, non-obese, healthy adults (mean age 48±10 yrs, 50% F).

Methods: BRs was assessed by computer analysis of 10 min beat-to-beat BP and ECG recordings obtained in resting supine. The linear regression slope of spontaneous concomitant increases or decreases in systolic BP and RR interval were calculated, averaged and expressed as total slope of BRs (ms/mmHg). Simultaneous records of pulse waveform were obtained by means of a validated oscillometric device for ABPM (Mobil-O-Graph NG, IEM, Stolberg, Germany) with in-built transfer-function like method, and pulse wave velocity (PWV, m/s) was assessed. BPV was assessed for systolic and diastolic BP as 24h standard deviation (SD), weighted 24h SD (wSD), daytime and night-time SD from 24h ABPM.

Results: In multiple linear regression analysis AS (assessed through PWV), had the strongest effect on BRs variation (beta=-0.50, p<0.0001), followed by HR and male sex. No significant effect was observed for age or MAP on BRs (See table). A similar independent analysis, showed a significant inverse relationship between BRs and daytime systolic BP SD (beta=-0.23; p=0.036).

Conclusion: Our findings suggest that in normotensive, otherwise healthy adults, decreased BRs and, indirectly, the associated increased day-time systolic BPV might be largely explained by an increased AS, independently of age and BP levels.

During exercise, increased xPI was independently associated with reduced WM (β=0.54, p=0.006) volumes only in T2DM independent of age, sex, heart rate, and 24-hour ambulatory SBP.

Conclusions: In T2DM, aortic reservoir function and transmission of excess pressure during exercise is associated with brain atrophy. These findings suggest that vascular mechanisms underlying structural brain changes may differ between healthy individuals and those with T2DM.

P4.16
INSULIN RESISTANCE IS ASSOCIATED WITH INCREASED LARGE ARTERY STIFFNESS IN NORMOTENSIVE HEALTHY ADULTS

J. E. Ochoa 1,3, M. M. Correa 2, A. M. Valencia 1, J. G. McEwen 1, J. A. Gallo 2, G. Bilo 3, P. Salvi 1, D. Aristizabal 2, G. Parati 1,3

1Department of Clinical Medicine and Prevention, University of Milano-Bicocca, Milan, Italy
2Corporación para Investigaciones Biologicas, Clinical and Research Center, SICOR, Medellin, Colombia
3Department of Cardiology, S. Luca Hospital, Istituto Auxologico Italiano, Milan, Italy

Aim: At present there is limited evidence on the relationship between insulin resistance (IR) and measures of large artery stiffness (AS) and wave reflections in normotensive healthy adults. Aim of the present study was to explore this issue in 90 normotensive (Systolic(S) blood pressure(BP) 107.1±9.3; diastolic (D) BP 69.6±7.7 mmHg), normoglycemic, non-obese, otherwise healthy adults (mean age 48 ± 10 yrs, 50% female).

Methods: IR was assessed with HOMA-Index and subjects were classified into IR tertiles, based on the distribution of HOMA-index values. Recordings of pulse waveform were obtained by means of a validated oscillometric device (Mobil-O-Graph NG, IEM, Stolberg, Germany) for ambulatory BP monitoring with in-built transfer-function like method. Aortic pulse wave velocity (PWV, m/s) and other measures derived from pulse wave analysis such as augmentation index (AIx, %), central SBP (cSBP), central DBP (cDBP) and central pulse pressure (cPP) were computed. Peripheral SBP and DBP, and heart rate (HR) were recorded and pulse pressure (PP) calculated as the difference between SBP and DBP.

Results: After multiple regression analysis adjusting for age, sex, HR and BMI, there was a significant overall effect of IR on measures of large artery stiffness and in central and peripheral BP levels. IR was associated with increased aortic PWV, and with higher central and peripheral SBP and DBP levels. See table.

Conclusion: our results indicate that in normotensive, healthy adults, IR may induce significant increases in large artery stiffness (as assessed with aortic PWV) and in central and peripheral BP levels.
