Abstract. The ability of children to interact with peers and adults according to generally accepted social norms and rules of behavior in society allows them to adapt to new social conditions. Children with visual impairments are characterized by certain features associated with the sensory sphere, which limit their opportunities for getting information from the outside world, lead to changes in the methods and means of communication, and cause difficulties for social adaptation and gaining social experience. The ability of children to predict future events may serve as an indicator of how well they orient themselves in social reality.

The purpose of the study was to identify the correlation between the forecasting capability of children and indicators of socialization of preschoolers with visual impairments. The study involved 249 children aged 5-7 years who attend preschool educational institutions – 210 children with no visual impairment and 30 children with visual impairment.

The results of the current study suggest that children with visual impairments have difficulties with social adaptation, gaining social experience and learning the rules in a normative situation. The limited opportunities for obtaining information from the outside world make it difficult for them to develop means of communication with adults and peers. Children with visual impairments find it harder to master the skills of caring for their things, not always do they follow safety rules in interaction with strangers and in their behavior, and their interaction with adults is often restricted. Children with visual impairments are less successful in free communication with adults and peers; they are less likely to comply with safety rules and systematic requirements and observe daily rules in compare to children with no developmental disorders.

The study suggests the need for introduction of special activities aimed at developing the ability to anticipate future events and developing successful social behavior in children with visual impairments.

1. Introduction

Children interact with culture all the time, this interaction determines the success of socialization [1,2,3]. Social situation of development determines social relationships of a child with the people around him, and the main role is played by adults. The more a child is able to overcome natural egocentrism and subordinate one’s behavior to cultural standards, the more congruent to the culture his behavior seem in social interaction. Culture gives children the means that allow them to learn and explore the world, to express their feelings and to organize their behavior [4,5]. P.I. Barkhatova states that the culture of behavior is being formed by assimilating universal moral values, ethical norms of behavior, aesthetic culture [6].
Solntseva writes that Children with visual impairments are characterized by certain features associated with the sensory sphere, which limit their ability to get information from the outside world, lead to changes in methods and means of communication, and cause difficulties for social adaptation and gaining social experience. [7]. These factors may impede the assimilation of rules in a regulatory situation. T.Y. Shilina notes that preschoolers with visual impairments are characterized by a poor development of social development components such as understanding of moral norms, awareness of the rules of behavior, self-esteem, value orientations [8].

The danger of misunderstanding and non-compliance with norms and rules of behavior by children with impaired development leads to the development of problematic behavior [9,10,11] and significant disruption in socialization, which may cause secondary isolation of children [12,13,14]. Difficulties in understanding and mastering the norms and rules of social interaction make it difficult for a child with developmental disorders to socialize and adapt to new social conditions.

The ability of children to predict future events may serve as an indicator of how well they orient themselves in social reality. The ability to anticipate indicates a high level of the development of the ability to orient oneself in reality – both in cognitive and emotional-personal components. Intensive development of forecasting capability in preschool years makes it an important resource for positive socialization of children. This is especially important for children with disabilities who lack the ability to predict.

Kalyuzhin, P.V., Sirotkina, T.Y. pay attention to the fact that the peculiarities of emotional and anticipatory images of a possible result influence the whole nature of a child's activity [15]. Studies show that in the preschool period, children begin to construct future scenarios, which allows them to plan and prepare for the future. However, there are many other consequences – such as the role of developing foresight in anticipating possible dangers – that remain unexplored [16]. Moreover, young children are sensitive both to the goal of forecasting and to the strategy they choose [17].

After several empirical studies, foreign researchers have found that children's capability to recall past events and the ability to predict future events develop at the age of 3 - 5 years. It was found that by the age of 4 and 5, children are fully capable of reporting on events that took place yesterday and will happen tomorrow [18].

It has been also discovered that by the age of 4 children acquire basic cognitive components necessary for the mental construction of specific future events [19]. Prediction of an emotional response to future opportunities implies the ability to model situations mentally. Young children gradually master the ability to represent future events at the age of 3 – 5 years (Atance & Jackson, 2009; Atance & Meltzoff, 2005; McCormack & Atance, 2011; Redshaw & Suddendorf, 2013; Suddendorf & Moore, 2011) [20, 21, 19, 22]. Although this skill continues to evolve in subsequent years, it is precisely the end of the preschool period when children undergo important events in a number of areas, such as self-awareness and reasoning about mental states that help to develop future-oriented thinking (Payne, Taylor, Hayne & Scarf, 2015; Suddendorf & Redshaw, 2013) [19]. General understanding of emotions is very important for effective forecasting, and at about 5 years of age, some significant events occur again – children start to realize that a person’s current emotions can be formed by a memory of the past or anticipation of the future (Lagattuta, 2014; Lagattuta, Wellman & Flavell, 1997) [23]. Reuter’s study shows that children can use several sources of information to predict subsequent words and revise forecasts before new linguistic information arrives [24].

2. Materials and methods

2.1. Research Methods

2.2. Participants
The study involved 249 children aged 5-7 years who attend preschool educational institutions. These include 210 children with no visual impairment and 30 children with visual impairments (strabismus, amblyopia, astigmatism).

2.3. Materials
Expert assessment of children's behavior was carried out using the method called "Psychological distress and atypical behavior scale" developed by A.M. Kazmina, N.A. Konovko, O.G. Salnikova, E.K. Tupitsina, E.V. Fedina.
- Monitoring of children in organized and free activity (A.G. Samokhvalova).
- Exploration of the specifics of communication and interaction of children with peers and adults, their social and emotional intelligence involved the "Emotional faces" method developed by N.Y. Semago. (Evaluation of adequacy, accuracy and quality of identification of the emotional state) [25].
- A set of techniques for determining the level of the development of preschoolers’ communicative skills (N.Y. Veraks): their understanding of the tasks set by adults in various situations of interaction; their comprehension of the state of peers and ideas about the ways of expressing their attitude towards adults and peers) [26].
- The technique "Determination of cultural congruence of the younger student" developed by L.F. Bayanova, T.R. Mustafina was used to determine the level of preschoolers’ understanding of social norms and values ("Obedience, meeting the expectations of an adult"; "Safety"; "Self-care, hygiene"; "Self-control") [27].
- The study of the features of prognostic activity involved the technique called “Try to guess” created by L. I. Peresleni and V. L. Podobed [28].

3. The results of the study
The results of the empirical study of forecasting indicators and skills of children with visual impairments are presented in Table 1.

Table 1. Descriptive statistics on indicators of socialization and forecasting in preschool children with visual impairments.

</table>
It was discovered that there are statistically significant differences (Student t-test, p < 0.001) among children in all indicators of the “cultural congruence” technique: “Obedience” (t = 5.51); “Security” (t = 2.14); “Hygiene” (t = 6.52); “Self-control” (t = 7.57). “Attitude towards adults” indicator of communicative development (t = 3.04) in children with visual impairments was also statistically lower than in normotypical children. Children with visual impairments understand and differentiate emotional states worse than their normotypic peers (t = 2.96).
We found a correlation between the “Prediction Errors” indicator – which reflects the efficiency of generating adequate forecasts as well as the ability to keep forecasts in mind, compare them and make inferences – and the “hygiene” indicator (r = .41) with understanding of the tasks set by adults in various situations of interaction (r = .52).

We have also revealed correlation links between the speed of forecast formation and indicators reflecting the level of communicative development which manifests itself in interaction with parents, caregivers and peers in regime moments (r = .42, r = .38, r = .43).

The “distraction error” indicator, which reflects the stability of volitional attention, correlates with obedience (r = .53): if child’s behavior meets expectations of an adult, he will be more focused on the thought that runs through the monologue or dialogue, he will carefully regulate communicative predictions; with self-care, hygiene (r = .63), with self-control (r = .50): if a child fulfills the requirements of an adult in hygiene standards and if he controls himself, he will not be distracted and will predict the course of communication and analyze further speech actions, he will think before shouting out or doing something; with indicators reflecting the level of communicative development, which manifests itself in interaction with educators and peers in regime moments (r = .52, r = .59), in organized activities (r = .51, r = .56), in free activities (r = .49, r = .46): a child can regulate the forecasting in these situations and it has a positive effect on communication skills.

The “reproduction” indicator is associated with a long-term memory, it is connected with the level of communicative development in interaction with peers during regime moments (r = .46): if a child engages in dialogue, interacts with peers during a walk or a wash, than he is more able to remember and reproduce previously predicted thoughts and rely on past communication experience.

The indicator is connected with child obedience (r = .45), hygiene (r = .42), with indicators of the level of communicative development in interaction with parents, caregivers in organized activities (r = .46) and free activity (r = .45).

4. Discussion and conclusions

Compliance with safety rules is a part of the culture of modern children which requires from them certain conformity and congruence with the culture. According to Obukhova L.F. in preschool years, controlled actions begin to dominate over impulsive ones [29]. Firstly, self-control is associated with the emergence of the subordination of motives, and secondly – with the beginning of the development of voluntary behavior in children, which means that a child of preschool age is able to control his behavior in a situation of social interaction. This thesis is confirmed by the results of our study. Children with no developmental disorders showed high results on the ”Self-control” factor – it proves the ability of children to control their emotional reactions and behavior in social situations.

The results of our study suggest that children with visual impairments have difficulties with social adaptation, gaining social experience and learning the rules in a normative situation. Limited opportunities for obtaining information from the outside world make it difficult for them to develop means of communication and with adults and peers.

In terms of socialization of children with different types of dysgenesis, the researchers point out the specific features of assimilation and reproduction of social connections and relations. A study by Guralnick [30] found that it is very difficult for visually impaired children to keep good interaction with their peers since there are certain limitations in their behavior caused by difficulties in obtaining information through vision. Studies have shown that children with visual impairments demonstrate playful behavior, which has primarily individual-exploratory nature, i.e. these kids do not seek to engage in collective games. Studies have revealed that children with developmental disabilities experience difficulties in social interaction – their behavior does not always meet the expectations of adults, they often violate the norms and rules of interaction in a situation of interaction with peers, which affects socialization of children. In addition, not in all situations do visually impaired children maintain self-control – they cannot always follow the rules of social interaction and control their actions.
Studies of Smirnov [31], Corsaro [32], Denham [33], Mirabile [34] emphasize the importance of friendly relations between children of preschool age, since they form the basis for understanding the rules of relationships and the ability to find adequate ways of expressing attitudes towards peers, which, under certain conditions of upbringing, develop into real motives and encourage children to take socially valuable behavior towards others. This study confirmed that the ability for self-control of children with visual impairment in social interaction is significantly lower in compare to their normotypic peers [35].

Empirical study helped to discover that in children with no developmental disorders, values of indicators for all factors of the methodology which reflect the level of cultural congruence and compliance with social norms and rules are significantly higher in compare to their peers with visual impairments. Children with normative development showed the highest results in the “Obedience” indicator, which reflects the congruence of children's behavior to the expectations of adults regarding typical rules of interaction in a normative situation. Children usually demonstrate honesty, respect for adults, they also organize their behavior in accordance with the requirements and expectations of adults. High results in the “Self-Control” indicator reflects the compliance of children's behavior with the rules providing for careful execution of tasks, accuracy, self-control of emotional reactions, attentiveness and restraint.

The study revealed that children with normative development show higher average values in all indicators of techniques. However, children with visual impairments showed higher average values on such scales as disassociation, anxiety, depression, disadaptiveness, hyperactivity in compare to their normotypical peers. Children with visual impairments showed lower results in the following indicators: “understanding of tasks”; “organized activity in a “child-peer” interaction situation; in “free activity in a “child – educator” situation of interaction; “reproduction”.

Child forecasting turned out to be determined by the child’s understanding of the rules and social norms: the better the child distinguishes and analyzes the task, the faster he is able to predict speech actions, answers to questions from an adult. The speed of forecast formation depends on the indicators reflecting the level of communicative development of a child, his interaction with parents, caregivers in organized and free activities.

5. Acknowledgments
The research was carried out with the financial support of the Russian Foundation for Basic Research under research project No. 19-013-00251 “Prediction as a resource for socialization of children with disabilities: the structural-functional model”.

We would like to thank the engagement and involvement of the research participants and their parents.
