ABSTRACT
Relationship rice between with height can be described with scatter diagram. Scatter diagram can produce the quadratic polynomial regression models and the cubic polynomial regression mode which possible. The quadratic polynomial regression model the best variable height and height² significant. Then parameter in the quadratic polynomial regression model can be estimated with Bayesian INLA with Gaussian and Empirical Bayes Strategy compare CCD, GRID Strategy. The posterior marginal intercept β₀, coefficient β₁ and β₂ with Gaussian method and different strategy product similar. The posterior marginal of random effects in the grid strategy different with CCD and empirical Bayes strategy.

Keywords: Relationship, scatter diagram, quadratic polynomial regression models, Gaussian method, Empirical Bayes Strategy, CCD Strategy, Grid Strategy, marginal posterior and Bayesian INLA.

1. INTRODUCTION
Regression analysis is statistical model used to study the relationship between one dependent variable with more than one independent variable [1]. The construction of a regression model that is suitable for statistical data associated with a “scatter diagram” of the variable. One regression model that is widely used is study the relationship of independent variable with dependent variable in the form of polynomial functions is polynomial regression.

The difficulty in the polynomial regression model is determining the degree of the polynomial model [2]. Determination of the degree of polynomial with the Bayesian approach has two choices. First determine the degree of polynomial which is a Bayes Factor and second the calculation of the posterior probability model using Bayesian Information Criterion by [3]. The method is used to compute the posterior distribution in the Bayesian model is the Markov Chain Monte Carlo. The Markov Chain Monte Carlo theory describes of the simulate data for several hours or days before convergence to the posterior distribution. If the model is more complex with many parameters, it will be difficult to determine the convergence and feasibility [4].

In 2009, Rue is developed Integrated Nested Laplace Approximation (INLA) as instead Bayesian MCMC Methods. INLA is approximate that has more speed and accuracy than MCMC [5]. Polynomial Regression has not been studied in more detail using the INLA approximation, so this study will discuss the use of INLA in polynomial regression in the relationship of height between with rice obtained. Based on the research background the issues that will be raised in this study are the following: 1) how to scatter diagram on data and determine polynomial regression model possible, 2) how the z parameterization of a polynomial regression model with Gaussian method which might
use the grid strategy, 3) how the z parameterization of a polynomial regression model with Gaussian methods which might use the CCD strategy, 4) how the z parameterization of a polynomial regression model with Gaussian methods which might use the empirical Bayes strategy.

2. STUDY LITERATURE

2.1 Polynomial Regression

If Y is response variable and x variable independent, then polynomial regression model with degree j (Mj) is

\[ Y = \beta_0 + \beta_1 x + \beta_2 x^2 + \cdots + \beta_j x^j + \varepsilon, \quad 0 < j \leq d \]  

There are two ways in choose degree j in model

a) Keep adding model until the added model is not significant variable
b) Star model with the highest degree the eliminate variable not significant [6]

2.2 The Integrated Nested Laplace Approximation.

Compute the parameter-parameter joint posterior distribution for model with Bayesian is used Markov Chain Monte Carlo is ran too long for more the complex model and many parameters [7]. In 2009, Rue proposes a way of approximating the marginal distribution. This compute the marginal distribution faster because is used numerical integration method [5].

2.3 Compute Bayesian INLA

If is use the Latent Gaussian Model in compute Bayesian INLA necessary the posterior marginal for latent parameter θ and hyperparameter ψ follows:

\[ p(\theta|y) = \int p(\theta_j|\psi, y) p(\psi|y) \, d\psi \quad j = 1, 2, \ldots, n_d \]  

and

\[ p(\psi_j|y) = \int p(\psi|y) \, d\psi_j \quad j = 1, 2, \ldots, s \]  

Equation (3) is not solution analytic then the posterior marginal for latent parameter θ with approximation:

\[ p(\theta|y) = \int p(\theta_j|\psi, y) p(\psi|y) \, d\psi \quad j = 1, 2, \ldots, n_d \]  

Equation (4) is not solution analytic then the posterior marginal for hyperparameter ψ with approximation:

\[ p(\psi_j|y) = \int p(\psi|y) \, d\psi_j \quad j = 1, 2, \ldots, s \]  

2.5. Approximation \( P(x|\psi, y) \)

The approximation to the marginals of the hyperparameters can be determined by marginalizing over \( \psi(\psi|y) \) above to obtain \( \psi(\psi|y) \). The approximation to the marginal of the latent effects require integrating the hyperparameters out and marginalizing over the latent effects.

2.6 Approximation \( P(\psi|y) \)

Rue et all [5] propose two different exploration schemes which requiring a reparameterization the Ψ space of several steps.

a) Compute mode \( p(\psi|y) \) is obtained by maximize \( \log p(\psi|y) \) on Ψ through Newton-Raphson Method.

b) Compute the negative Hessian H matrix on mode.

c) Compute the eigenvalue decomposition \( H^{-1} = V \Lambda V^T \)

d) With application the eigenvalue decomposition for each value of the hyperparameter Ψ can reparameterization z so that \( \Psi(z) = \Psi + VA^1/2z \) [8]

Log \( p(\psi|y) \) is explored using the z in three different schemes depending on the number of hyperparameters and required a reparameterization of Ψ space to make the density more regular [2]

i) Using s regular grid on step h centered on the mode \( x=0 \) and points in the grid are considered if \( \log p(\Psi(0)|y) - \log p(\Psi(z)|y) < \delta \) where \( \delta \) a given threshold. Working in along the axis in the z parameterization and all intermediate points that fulfill the previous condition are added. This will provide a set of configuration of the hyperparameters about the posterior mode that can be used in the numerical integration in popular the grid strategy.

ii) With CCD (central composite design) by [9] centered at \( \Psi(0) \) can be used so that a few strategically placed points are obtained. This can be more efficient that the grid strategy as the high dimension of the hyperparameter. The CCD strategy, a number of points that fill the space are chosen using a response surface design. Rue et al. [5], this CCD strategy worked well in many cases.

iii) Empirical Bayes strategy used the large number of hyperparameters that will plug the posterior mode of \( \psi|y \). The strategy will work when the variability in the hyperparameters does not impact the posterior of...
the latent effects \( x \). This strategy of plugin estimators can be used to fit high parameters model and they can provide good strategy in a number scheme.

### 2.7 Prior in INLA

Prior in Bayesian is use definition which is very carefully and describe in more detail. If not prior distribution a parameter use the default prior. Prior-prior in INLA are set in the internal representation of the parameter, which have the different scale of the parameter in the model [2].

### 3. RESULT AND DISCUSSION

#### 3.1 The Quadratic Polynomial Regression Model Bayesian INLA

**3.1.1. Data and scatter diagram**
