#### Abstract

Under the leadership of Professor Eric Yeh of Columbia University, the authors use nine carry models including No arbitrage pricing model, Iron condor model, Spot holding model, Cost of carry model, Premium selling model, Classic FX carry model, Convenience yield model, Collar trade model and FX transaction decision model to evaluate the return of commodity futures, options and forex respectively. Through the trading activities under the mechanisms of nine models respectively, PNLs of each asset are drawn and listed as follows.

Keywords: carry, commodity, option, FX, future

## 1.INTRODUCTION

Carry is the return of an asset obtained from holding it. There are three basic models in carry style called no arbitrage pricing model, iron condor model and spot holding model applied to commodity, option and FX respectively. These three models can be designed to help arrange discretionary trading of different assets to get profit. The mechanism of each basic model is as follows.

### 1.1 Commodity

-No arbitrage pricing model
According to the theory of cost of holding, there is a linkage relationship between future price and initial price in commodity market. Convenience income can be defined as the income of holding commodity inventory. If the convenience income is introduced into equation, the difference between the current contract's price and the future contract's price can be written as

$$
\mathrm{F}(\mathrm{t}, \mathrm{~T})-\mathrm{F}(0, \mathrm{~T})=\mathrm{CS}(\mathrm{t}, \mathrm{~T})-\mathrm{Cy}(\mathrm{t}, \mathrm{~T})
$$

$\mathrm{F}(\mathrm{t}, \mathrm{T})$ is the price of future contract at $\mathrm{t}(0<\mathrm{t}<\mathrm{T})$; $\mathrm{F}(0, \mathrm{~T})$ is the initial future contract's price; $\mathrm{CS}(\mathrm{t}, \mathrm{T})$ is the storage cost (holding cost). Storage cost includes fixed cost and variable cost. $\mathrm{Cy}(\mathrm{t}, \mathrm{T})$ is convenience income. Obviously, from the calculation formula, when the convenience income is lower than the holding cost, it means the price of future contract is higher at the expiration date. We choose the trading period 3/1/21-

3/26/21, every Monday and Friday, and the assets used to trade are crude oil, corn, cotton, rape oil, egg, starch, cotton yarn, rapeseed, apple, palm, jujube, peanut.

### 1.2 Option

## -Iron Condor model

An iron condor is an options strategy consisting of two puts (one long and one short) and two calls (one long and one short), and four strike prices, all with the same expiration date. The iron condor earns the maximum profit when the underlying asset closes between the middle strike prices at expiration. In other words, the goal is to profit from low volatility in the underlying asset. The maximum profit for an iron condor is the amount of premium, or credit, received for creating the four-leg options position. Maximum gain for the iron condor strategy is equal to the net credit received when entering the trade. Maximum profit is attained when the underlying stock price at expiration is between the strikes of the call and put sold. At this price, all the options expire worthless.

## Max Profit = Net Premium Received - Commissions Paid

Max ProfitAchieved When Price of Underlying is in between Strike Prices of the Shor Put and the ShortCall

We choose the trading period $3 / 1 / 21-3 / 26 / 21$, every Monday and Friday, and the assets used to trade are 50ETF Call April4200, 50ETF Call April3400, 50ETF Put April3600 and 50ETF Put April3900.

PRESS

### 1.3 FX

-Spot holding model
Borrow a certain amount of local currency A(short rate r 1 ) at sight. Then use the spot exchange rate $S$ to buy a certain amount of foreign currency and sells this foreign exchange future contract at price F (remaining maturity time t , short-term interest rate r 2 ) at the same time. Thus, the financing cost in the model depends on the local short-term interest rate r1, while the return depends on the foreign short-term interest rate r 2 . When it becomes equilibrium, spot maturity value $=$ futures maturity value, which can be expressed as:

$$
A S\left(1+r_{1} t\right)=A F\left(1+r_{2} t\right)
$$

The equation can also be expressed as:

$$
F=S \frac{1+r_{1} t}{1+r_{2} t}
$$

So if $\mathrm{F} / \mathrm{S}=1+\mathrm{r} 1 \mathrm{t} / 1+\mathrm{r} 2 \mathrm{t}>1$, which means $\mathrm{F}>\mathrm{S}$, buy long. If not, sell short.

We choose the trading period $3 / 1 / 21-3 / 26 / 21$, every Monday and Friday, and the FX futures used to trade are USDAUD, GBPAUD, CADAUD, GBPCAD, EURCAD, CHFCAD, EURHKD, USDHKD, GBPHKD, CADCHF, GBPCHF, USDCHF.

## 2.DISCRETIONARY TRADING

### 2.1 Commodity

PNL. Trading period: 3.1-3.5
The reason we choose crude oil is that the price tend to increase when it close to summer, during the months before summer the oil factories always do the maintenance and decrease the output of crude oil. So its holding cost tends to be lower than convenience income and we should buy and holding it to make profit. The reason we choose corn to short is that nowadays the holding cost of corn is becoming low because of the technical improvement, and the corn stock is high so under the influence of demand\&supply, the price of corn would go down. In March 2021, the domestic cotton market, after the festival downstream production orderly recovery, lint sales continue to be active, the traditional peak season of the textile industry is coming, it is expected that the short-term domestic cotton price will continue to rise. In the international market, the growth rate of the total number of confirmed cases in the world slows down, the market's expectation of economic recovery continues to rise, and the cotton price at home and abroad is expected to continue to rise in the short term.

Crude oil (t)
Initial contract price $F(0, T) / 3.1$. $¥ 415.2$,

Holding cost $=50, \mathrm{C}=\mathrm{r}+\mathrm{s}-\mathrm{y}, \mathrm{r}=4.35 \%, \mathrm{~s}=4 / 415.2=0.9 \%$, $\mathrm{c}=12 \%, \quad \mathrm{y}=-6.75 \%, \mathrm{Cy}=\mathrm{y} *$ initial price $=-¥ 28.026$,Cs$\mathrm{Cy}=78.026>0$. Thus, $\mathrm{F}(\mathrm{t}, \mathrm{T})>\mathrm{F}(0, \mathrm{~T})$, should buy long.

Corn (t)
Initial contract price/3.1. $\quad ¥ 2789$
Holding cost=¥2200/52=42, C=r+s-y, r=4.35\%, $\mathrm{s}=5 / 2789=0.5 \%, \quad=42 / 2789=1.5 \%$, $y=3.35 \%, C y=¥ 93.43, \mathrm{Cs}-\mathrm{Cy}=-51.43<0$. Thus, $\mathrm{F}(\mathrm{t}, \mathrm{T})-$ $\mathrm{F}(0, \mathrm{~T})<0$, sell short.

Cotton (t)
Initial contract price/3.1. ¥16685

$$
\begin{aligned}
& \text { Holding cost }=¥ 1700, \quad \begin{array}{r}
\mathrm{C}=\mathrm{r}+\mathrm{s}-\mathrm{y}, \quad \mathrm{r}=4.35 \%, \\
\mathrm{c}=1700 / 16685=10 \%, \\
\mathrm{~s}=700 / 16685=4 \%, \\
\mathrm{y}=-1.65 \%, \quad C y=-275.3, \quad \text { Cs-Cy}=1975.3>0 . \quad \text { Thus, } \\
\mathrm{F}(\mathrm{t}, \mathrm{~T})-\mathrm{F}(0, \mathrm{~T})>0 \text {, should buy long. }
\end{array}
\end{aligned}
$$

Learn from these absolute values, the biggest number is 1975.3 of Cotton. The higher the absolute number, the higher the possibility to get more profit. According to the comparison, the possibility of making profit of cotton is the highest. So the highest investment on cotton.1975.3/(78.026+51.43+1975.3) $=93.87 \%$ of $¥ 300 \mathrm{k}=¥ 281.61 \mathrm{k}$. Investment on corn. $2.44 \%$ of $¥ 300 \mathrm{k}=¥ 7.32 \mathrm{k}$, Investment on crude oil. $3.69 \%$ of $¥ 300 \mathrm{k}=¥ 11.07 \mathrm{k}$. Future price $(\mathrm{F}(\mathrm{t}, \mathrm{T})) / 3.5$ : Crude oil. 428.4. $\mathrm{PNL}=(11.07 \mathrm{k} / 415.2) * 428.4-11.07 \mathrm{k}=351.9$ profit, Corn. 2819. PNL=7.32k(7.32k/2819)*2789=77.90profit, Cotton. 15990. PNL=(281.6k/16685)*15990-281.6k=-11729.82loss, Portfolio profit=¥-11300loss.

PNL. Trading period: 3.8-3.12
We choose rape oil to long because it is estimated that its price would increase. This round of food oil price rise is affected by many factors, such as the increase of import cost and domestic soybean purchase price, the rise of agricultural products and inflation expectations, as well as the demand for goods in peak sales season. We choose egg to short because its price tendency is dropping down. After the very serious coronavirus period, see the egg market began to improve, many farmers began to raise layers. The supply of eggs began to increase significantly. After the epidemic, the economy as a whole was weak, and the consumption desire of ordinary citizens was not strong. In addition, after the epidemic ended, pork prices began to fall sharply, and the domestic demand for eggs decreased, resulting in a sharp drop in egg prices. We choose corn starch because recently its price is decreasing. In order to stabilize the market demand for corn, the Ministry of Finance suspended the purchase of VAT Deduction Policy. The Ministry of Finance issued a notice saying that in order to control the rapid development of corn deep processing, it will suspend the value-added tax deduction policy for corn deep processing enterprises.

PRESS

Sources said that the suspension of tax deduction policy should be to calm the market demand for corn.

Rape oil ( t )

## Initial contract price $\mathbf{F}(\mathbf{0}, \mathbf{T}) / \mathbf{3 . 8} \quad \mathbf{¥ 1 1 0 3 5}$

Holding cost $=¥ 115, \quad \mathrm{C}=\mathrm{r}+\mathrm{s}-\mathrm{y}, \quad \mathrm{r}=4.35 \%$, $\mathrm{s}=30 * 52 / 11035=14.1 \%, \quad \mathrm{c}=115 / 11035=1.04 \%$, $\mathrm{y}=17.41 \%, \quad \mathrm{Cy}=\mathrm{y}$ *initial price=-3956, $\mathrm{Cs}-\mathrm{Cy}=9956>0$. Thus, $\mathrm{F}(\mathrm{t}, \mathrm{T})>\mathrm{F}(0, \mathrm{~T})$, should buy long.

Egg (0.5t)

## Initial contract price/3.8 $\mathbf{¥ 4 3 8 0}$

Holding cost=¥2700/52=¥52, $\quad \mathrm{C}=\mathrm{r}+\mathrm{s}-\mathrm{y}, \mathrm{r}=4.35 \%$, $\mathrm{s}=25 / 4380=0.5 \%, \mathrm{c}=52 / 4380=1.1 \%$, $\quad \mathrm{y}=3.75 \%$, $\mathrm{Cy}=¥ 164.25, \mathrm{Cs}-\mathrm{Cy}=-112.25<0$. Thus, $\mathrm{F}(\mathrm{t}, \mathrm{T})-\mathrm{F}(0, \mathrm{~T})<0$, sell short.

## Starch (t)

## Initial contract price/3.8. $\quad ¥ 3346$

Holding cost $=¥ 1100, \quad \mathrm{C}=\mathrm{r}+\mathrm{s}-\mathrm{y}, \quad \mathrm{r}=4.35 \%$, $\mathrm{s}=500 / 3346=14.9 \%, \quad \mathrm{c}=1100 / 3346=32.8 \%$, $\mathrm{y}=-13.55 \%, \quad \mathrm{Cy}=-453.3, \quad \mathrm{Cs}-\mathrm{Cy}=1553.3>0$. Thus, $\mathrm{F}(\mathrm{t}, \mathrm{T})-\mathrm{F}(0, \mathrm{~T})>0$, should buy long

Learn from these absolute values, the biggest number is 284.4 of Rape oil. The higher the absolute number, the higher the possibility to get more profit. According to the comparison, the possibility of making profit of rape oil is the highest. So the highest investment on rape oil. $9956 /(9956+112.25+1553.3)=85.67 \%$ of $¥ 300 \mathrm{k}=257 \mathrm{k}$, Investment on egg $0.97 \%$ of $¥ 300 \mathrm{k}=¥ 2.90 \mathrm{k}$, Investment on starch. $13.36 \%$ of $¥ 300 \mathrm{k}=¥ 40.08 \mathrm{k}$, Future price $(\mathrm{F}(\mathrm{t}, \mathrm{T})) / 3.12$ : Rape oil. $10724 \quad \mathrm{PNL}=(257 \mathrm{k} / 11035) * 10724-257 \mathrm{k}=-7240 \mathrm{loss}$, Egg. 4519 PNL=2.90k-(2.90k/4519)*4380=90profit, Starch. 3242. PNL=(40.08k/3346)*3242-40.08k=1246loss

## Portfolio profit=¥-8396loss

PNL. Trading period: 3.15-3.19
We choose cotton yarn to long because that for the driving force conversion, from raw materials, supply and demand driven to "inventory driven", in this way the price of cotton yarn was increased. We choose rapeseed to short because affected by African classical swine fever, the domestic rapeseed market supply is not much, and the traders generally take the goods, so the market demand for meal is weak. We choose apple to long because these years the price of apple is climbing continuously. Increasing labor costs are one of the reasons for Apple's price rise. Also there are not many apples in cold stores all over the country.

Cotton yarn ( t )
Initial contract price $\mathbf{F}(\mathbf{0}, \mathbf{T}) / \mathbf{3 . 1 5}$. $\mathbf{¥ 2} 2515$

Holding cost $=¥ 1000, \quad \mathrm{C}=\mathrm{r}+\mathrm{s}-\mathrm{y}, \quad \mathrm{r}=4.35 \%$, $\mathrm{s}=60 / 22515=0.27 \%, \quad \mathrm{c}=22.2 \%$, $\quad \mathrm{y}=-17.58 \%$, $\mathrm{Cy}=\mathrm{y}$ *initial price $=-¥ 3.96$, Cs$\mathrm{Cy}=1000+3.96=1003.96>0$. Thus, $\mathrm{F}(\mathrm{t}, \mathrm{T})>\mathrm{F}(0, \mathrm{~T})$, should buy long.

Rapeseed (t)
Initial contract price/3.15. $\quad \mathbf{x} 992$
Holding cost=$¥ 50, \quad \mathrm{C}=\mathrm{r}+\mathrm{s}-\mathrm{y}, \quad \mathrm{r}=4.35 \%$, $\mathrm{s}=30 / 5992=0.5 \%, \quad \mathrm{c}=50 / 5992=0.83 \%, \mathrm{y}=4.02 \%$, $С у=¥ 240.88, \quad \mathrm{Cs}-\mathrm{Cy}=50-240.88=-190.88<0$. Thus, $\mathrm{F}(\mathrm{t}, \mathrm{T})-\mathrm{F}(0, \mathrm{~T})<0$, sell short.

Apple (t)

## Initial contract price/3.15. ¥4939

Holding cost $=¥ 1700, \quad \mathrm{C}=\mathrm{r}+\mathrm{s}-\mathrm{y}, \quad \mathrm{r}=4.35 \%$, $\mathrm{s}=700 / 4939=14.2 \%, \mathrm{c}=1700 / 4939=34.4 \%, \quad \mathrm{y}=-15.8 \%$, $\mathrm{Cy}=-¥ 780.4$, Cs-Cy=2480.4>0. Thus, $\mathrm{F}(\mathrm{t}, \mathrm{T})-\mathrm{F}(0, \mathrm{~T})>0$, should buy long.

Learn from these absolute values, the biggest number is 2480.4 of Apple. The higher the absolute number, the higher the possibility to get more profit. According to the comparison, the possibility of making profit of apple is the highest. So the highest investment on apple. $2480.4 /(1003.96+190.88+2480.4)=67.49 \%$ of $¥ 300 \mathrm{k}=¥ 202.47 \mathrm{k}$

Investment on rapeseed. $5.19 \%$ of $¥ 300 \mathrm{k}=¥ 15.57 \mathrm{k}$. Investment on cotton yarn. $27.32 \%$ of $¥ 300 \mathrm{k}=¥ 81.96 \mathrm{k}$, Future price $(\mathrm{F}(\mathrm{t}, \mathrm{T})) / 3.19$ :

$(202.47 \mathrm{k} / 5992) * 5828=5542$ profit
Portfolio profit=8706profit
PNL. Trading period: 3.22-3.26
We choose palm to short because recently its price is affected by several factors, India raises tariffs, Malaysia's palm oil exports slowed and EU plans to ban palm oil. In recent years, jujube is easy to rot in large area after coloring in rainy days, which may be due to the weather. In contrast, in rainy days, the degree of decay of gray jujube is not so high, and the empty skin is less, so many farmers change the jujube tree into gray jujube. So the jujube is not that popular among people and the price decreased as a result. The price of peanut is going down affected by the purchase quantity of oil factory, export order and domestic market demand. Generally speaking, it is the problem of market demand. Thus, we choose this

PRESS
commodity to sell short to get return.
Palm(t)

## Initial contract price $\mathbf{F}(\mathbf{0}, \mathbf{T}) / \mathbf{3 . 2 2} \quad ¥ 7802$

Holding cost=620/52=11.9, C=r+s-y, r=4.35\%, $\mathrm{s}=4 / 7802=0.05 \%, c=11.9 / 7802=0.15 \%, \quad \mathrm{y}=4.25 \%$, $\mathrm{Cy}=\mathrm{y}$ *initial price $=331.5, \quad \mathrm{Cs}-\mathrm{Cy}=-319.6<0$. Thus, $\mathrm{F}(\mathrm{t}, \mathrm{T})<\mathrm{F}(0, \mathrm{~T})$, should sell short.

Jujube(t)

## Initial contract price/3.22 ¥9745

Holding cost $=¥ 73, \quad \mathrm{C}=\mathrm{r}+\mathrm{s}-\mathrm{y}, \quad \mathrm{r}=4.35 \%$, $\mathrm{s}=165 / 9745=1.6 \%, \mathrm{c}=73 / 9745=0.7 \%$, $\quad \mathrm{y}=3.45 \%$, $\mathrm{Cy}=¥ 336.2, \quad \mathrm{Cs}-\mathrm{Cy}=-263.2<0$. Thus, $\mathrm{F}(\mathrm{t}, \mathrm{T})-\mathrm{F}(0, \mathrm{~T})<0$, sell short.

## Peanut(t)

## Initial contract price/3.22. ¥10480

Holding cost=¥6000/52=115.3, $\mathrm{C}=\mathrm{r}+\mathrm{s}-\mathrm{y}, \mathrm{r}=4.35 \%$, $\mathrm{s}=23 / 10480=0.2 \%, \mathrm{c}=115.3 / 10480=1.1 \%, \quad \mathrm{y}=3.45 \%$, $\mathrm{Cy}=361.56$, $\quad \mathrm{Cs}-\mathrm{Cy}=-301.9<0 \quad$ Thus, $\mathrm{F}(\mathrm{t}, \mathrm{T})-\mathrm{F}(0, \mathrm{~T})<0$, should sell short.

Learn from these absolute values, the biggest number is of jujube. The higher the absolute number, the higher the possibility to get more profit. According to the
comparison, the possibility of making profit of rape oil is the highest. So the highest investment on palm $319.6 /(319.6+263.2+301.9)=36.13 \%$ of $¥ 300 \mathrm{k}=$ $¥ 108.39 \mathrm{k}$, Investment on Jujube $29.75 \%$ of $¥ 300 \mathrm{k}=¥ 89.25 \mathrm{k}$, Investment on Peanut $34.12 \%$ of $¥ 300 \mathrm{k}=¥ 102.36 \mathrm{k}$, Future price $(\mathrm{F}(\mathrm{t}, \mathrm{T})) / 3.26$ : Palm. 7524 PNL=108.39k-(108.39k/7802)*7524=3862profit, Jujube. $9740 \quad$ PNL=89.25k$(89.25 \mathrm{k} / 9745) * 9740=45.8$ profit, Peanut. 10510. ## 3. SYSTEMATIC TRADING

### 3.1 Commodity

-cost of carry model
In order to avoid inter-temporal arbitrage, the cost of carry model is established based on forward futures price and short-term futures price. Trading rules: On the one hand, when the price of forward futures is higher than that of short-term futures and the holding cost from shortterm holding to long-term holding is eliminated, the trader will sell forward futures and buy short-term futures for arbitrage. In order to prevent arbitrage, the price of forward futures should not be greater than the sum of the price of recent futures and the corresponding holding cost.

## $\mathrm{Fd} \leq \mathrm{Fn}\left(1+\mathrm{C}^{\prime}\right)$

Here, Fd is the current price of further futures, Fn is the current price of closer futures, and $\mathrm{C}^{\prime}$ is the fraction of holding cost. On the other hand, if the forward futures price is relatively lower than the recent futures price, there will be a buyer's forward futures contract and sell the recent futures contract for arbitrage. In order to prevent arbitrage, the relationship between Fn and Fd should be as follows:

## $\mathrm{Fd} \geq \mathrm{Fn}\left(1+\mathrm{C}^{\prime}\right)$ <br> So: $\mathrm{Fd}=\mathrm{Fn}\left(1+\mathrm{C}^{\prime}\right)$ (signal)

The assets used are cotton and sugar and the trading period 3/14/16-3/14/21. Source of data: The data used

Total return
30302.800

79

Figure 4 : According to the graph, the general trend is climbing. Some little fluctuation exists under the influence of weather but the total return is positive and the performance is favorable.

### 3.2 Option

-Premium selling model
Trading rules: Buy a put option and sell it when the underlying assets' price is lower than the exercise price, and in this way we can get return through premium
selling. If have a right judgement about the market condition, we're supposed to close a position and get infinite profit. However, if has a wrong judgement about the market, the biggest loss is the payment for the option. Source of data: The data used comes from 50ETF in wind, opening and closing prices of every quarter from $3 / 14 / 16$ to $3 / 12 / 21$. The assets used to trade are 10 options in 50ETF and trading period 3/14/16-3/12/21.

Figure 5: According to the graph, the quarterly returns are always positive, settling in the range $(0,10000)$ with quarterly investment $¥ 10000$ apart from the period June- September in 2018. Therefore, with the outcome of calculation, we can know we successfully get return during the trading period.

### 3.3 FX

## -Classic FX carry model

$\mathrm{C}=$ return of carry, S is the price of FX contract, F is the future's price. r' is the foreign short-term interest rate and $r$ is local interest rate. Trading rules:

$$
C_{t}=\frac{S_{t}-F_{t}}{F_{t}}=\left(r_{t}^{f *}-r_{t}^{f}\right) \frac{1}{1+r_{t}^{f}}
$$

First of all, there are two ways to calculate the carry value of foreign exchange at each trading time point. One is to directly use the nominal interest rate of the bank of the country to calculate the interest rate difference. The other is to calculate the difference of the prices between spot and future. After the calculation of the rightmost value, we can know the direction of S-F, and if it is positive, $S>F$, we're supposed to sell short. Source of data: The data of these assets is found from the futures market, the opening and closing data of every quarter among the period $3 / 14 / 16-3 / 15 / 21$.

Table 12: Classic FX carry model

## 4.ADVANCED MODEL

### 4.1 Commodity

CYM-Convenience yield model

$$
\begin{align*}
& \quad F_{t, T}=e^{[r+m](T-t)} S_{t}^{A}=e^{[r+m](T-t)} \frac{S_{t}^{C}}{e^{c_{t}(T-t)}}= \\
& e^{[r+m-c y](T-t)} S_{t}^{C} \tag{5}
\end{align*}
$$

$F$ is the price of forward contract, $S$ is spot price, $r$ is risk-free rate, m is rate of storage cost, Cy is convenience yield and t is one day between the beginning and the expiration date. Define the leftmost side of the formula to be A and rightmost side B . When $\mathrm{A}=\mathrm{B}$, the signal exists, then do trading activities to get return. Trading rules: If $A>B$, we're supposed to buy forward with price F and borrow spot commodities then carry them for a period, during the period, $S$ turns to $B$ under the influence of storage costs, convenience yield and interest rate. Finally, at the expiration date we can sell the commodity through which get a net profit $A-B>0$. If $A<B$, we're supposed to buy long-forward with price F and sell spot commodities with S , then use the money earned to do risk-free investments, in this way during the trading period the revenue is B and get the net profit $\mathrm{B}-\mathrm{A}>0$ in the end. We choose the trading period $1 / 1 / 21-3 / 1 / 21$ and the assets used to trade are crude oil, gold, soybean.

### 4.2 Option

## Collar Trade Model

This trading strategy consists of the following three parts:
(1). Buy stocks
(2). long ATM or OTM put
(3). short OTM call

We can understand it easily by an example. The stock $A B C$, let's say it's now trading at $\$ 45$.
(1). Buy 100 shares of ABC
(2). Buy a PUT with a strike price of 45 for $\$ 5.00$
(3). Sell 1 strike with a call price of 60 at $\$ 3.00$

Let's look at the likelihood on the upside first:
Trading rules: When the stock goes up over 47 and below 60, your stock is making money. You've got back
the money you sold the Call. The Call is also making money.

When the stock goes up more than 60 years, the stock is making money, but because you sold the Call, it doesn't matter how much it goes up. The Call you sell is prepaid for you.

When the stock goes down, because you bought a Put of 45 , you can sell your stock for 45 even if the stock goes down to 20. Stocks are break-even. And because the stock goes down, you make the money you made selling the Call. You only lose the difference between the price you paid to buy the Put and the price you sold the Call, which is $\$ 2$. Per share you spend $=\$ 45+\$ 5-\$ 3=\$ 47$, Your maximum risk per share $=\$ 47-\$ 45=\$ 2$

Your maximum profit per share $=\$ 60-\$ 47=\$ 13$. This approach is a good one for stocks that are in doubt.

Collar Carry Trade:

$$
S+P_{x 1}-C_{x 2}, x 1 \leq x 2
$$

Expiration date profit formula:

$$
\begin{aligned}
\mathrm{P}_{\mathrm{L}}=\mathrm{S}_{\mathrm{T}} & -S_{0}+\operatorname{Max}\left(0, \mathrm{X}_{1}-\mathrm{S}_{\mathrm{T}}\right)-\mathrm{P}_{1} \\
& -\operatorname{Max}\left(0, \mathrm{~S}_{\mathrm{T}}-\mathrm{X}_{2}\right)+\mathrm{C}_{2}
\end{aligned}
$$

When

$$
\begin{aligned}
& \mathrm{S}_{\mathrm{T}} \leq \mathrm{X}_{1} \leq \mathrm{X}_{2}, \mathrm{P}_{\mathrm{L}}=\mathrm{X}_{1}-\mathrm{S}_{0}-\mathrm{P}_{1}+\mathrm{C}_{2} \\
& \mathrm{X}_{1}<\mathrm{S}_{\mathrm{T}} \leq \mathrm{X}_{2}, \mathrm{P}_{\mathrm{L}}=\mathrm{S}_{\mathrm{T}}-\mathrm{S}_{0}-\mathrm{P}_{1}+\mathrm{C}_{2} \\
& \mathrm{X}_{1} \leq \mathrm{X}_{2}<\mathrm{S}_{\mathrm{T}}, \mathrm{P}_{\mathrm{L}}=\mathrm{X}_{2}-\mathrm{S}_{0}-\mathrm{P}_{1}+\mathrm{C}_{2}
\end{aligned}
$$

The stockholder became concerned about the possibility of a decline in the stock and decided to buy put options on his stock as protection. But he was frustrated by the cost of putting options, so he also considered selling calls. If he buys an undervalued put, he is likely to sell a call, and his earnings will more than cover the cost of the put, so he can set up a week of protective collar arbitrage at no cost. At least no debt. His "cost" is forgoing the stock's potential gain on the exercised value of the sold call option. As shown in figure 1 , the collar option model, which is a way of managing the cost overrun caused by change orders, consists of the insurance buyer's section of striking a call option according to the increase in cost overrun and the insurance seller's section of striking a put option according to the decrease in cost overrun. If S0is the current expected loss due to the cost overrun at present $(\mathrm{t}=0), \mathrm{S} 0$ is within the range of the strike price $(\mathrm{Xp})$ of the put option and the strike price (Xc) of the call option.

PRESS

Figure 7: Concept of material contract model based on collar option.

When the actual cost overrun caused by change orders exceeds the estimate, and $S$ exceeds Xc , the insurance buyer exercises the call option, realizing the call option value shown in. Therefore, Xc of the call option indicates the maximum permissible limit of the cost overrun caused by change orders in the corresponding project. In other words, the insurance becomes meaningless when the cost overrun is lower than Xc; i.e., the value of the insurance becomes zero. However, when the cost overrun exceeds Xc, the insurance creates value because a hedge on the cost overrun can be placed through the insurance. In this case, the insurance seller's side incurs a loss that is proportionate to the avoidance of the cost overrun caused by change orders placed through the insurance by the insurance buyer.

Figure 8: Value of insurance depending on the increase in the cost overrun

If the actual cost overrun caused by change orders is lower than expected, and S is below Xp , the insurance seller exercises the put option, realizing the put option value shown in figure 3. Therefore, Xp of the put option indicates the starting point from which the insurance seller can secure a fee for providing insurance without baseline cost. In other words, when the cost overrun is lower than Xp, the potential net profit margin of the insurance buyer is restored to the insurance seller.

Figure 9: value of fee depending on the decrease in cost overrun

In summary, the insurance premium is not fixed. When the cost overrun caused by change orders is lower than Xp , the insurance buyer pays the difference between the Xp value and the cost overrun as the insurance premium to the insurance seller. Therefore, the insurance premium varies according to changes in the cost overrun caused by change orders. We choose the trading period $1 / 1 / 21-3 / 1 / 21$ and the assets used to trade are index.

### 4.3 FX

Foreign exchange transaction decision model
In general, as the demand for a particular foreign currency increases, the amount of that foreign currency that can be exchanged per unit of currency gradually decreases. Our basic assumption is that foreign exchange transactions are allowed within a sufficiently large quantitative range, but that exchange rates are set at different constants for different quantitative ranges within this range. For instance, assume M is a sufficiently large number and $\mathrm{xi}, \mathrm{j}$ is the amount of currency i used to exchange currency j , $\mathrm{Ri}, \mathrm{j}(\mathrm{xi}, \mathrm{j})$ is the number of currency j gained. When the trading quantity xi,j between 0 and a, the exchange rate equals to $r(1)$. When the trading quantity $x i, j$ between a and M , the amount no large than a can be exchanged by $r(1)$, the exceeded part can be exchanged by the rate $r(2)$. In general, assume the trading range of any two kinds of currencies is from 0 to M . And assume the amount of exchange rate changing range of every two FX is q. The exchange

PRESS
rate is a constant $\mathrm{r}(\mathrm{t})$ when $\mathrm{xi}, \mathrm{j}$ among $\mathrm{C}(\mathrm{t}-1)-\mathrm{C}(\mathrm{t})$, $\mathrm{t}=1,2 \ldots \ldots, \mathrm{q}$.

Trading rules:
In the following formula, ak means the given amount of currency k. And in the trading network, there exists $n$
vertexes. The vertexes create totally $n(n-1)$ arcs, every arc has the restriction 0 and M . xi,j is the amount of currency $i$ used to exchange currency $j$. Ri, $j(x i, j)$ is set on the range from 0 to $\mathrm{M}, \mathrm{M}$ is a sufficiently large number. We can use the formula to calculate the maximum cash flow at vertex I in this network.

$$
R_{i, j}\left(x_{i, j}\right)= \begin{cases}r_{i, j}^{(H)} x_{i, j} & 0 \leqslant x_{i, j} \leqslant a \\ i_{i, i, j}^{(i)} a+r_{i, j}^{(a)}\left(x_{i, 1}-a\right), & a \leqslant x_{i, 1} \leqslant M\end{cases}
$$

## ( $\mathrm{P}_{\mathrm{o}}$ ) Max v

We choose the trading period $1 / 1 / 21-3 / 1 / 21$ and the assets used to trade are G10.

## 5.CONCLUSION

### 5.1 Summary

Some typical profitable trading model for different assets are listed as follows. Spot holding model is a model applied to FX, forecasting the price from the ratio of interest rates of currencies. We use the gap between the financing cost and interest return from two different currencies' interest rates to get profit. Through the analysis of trading results, we can know that portfolio return is positive using the formula from trading model. So we can use this to trade. Cost of carry model is a model applied to commodity, we should focus on the value of forward futures and short-term futures with holding cost, when there exist a signal(the value of two sides becomes equal). Then do short or long depending on the direction of the formula in the model to get profit. Through the application of carry model, some kinds of commodities reach high return. For example, the trading of cotton has good performance using this model. Classic FX carry model is a model applied to FX, from the comparison of normal interest rates difference and the difference of prices between spot and future, we can make the decision to buy long or sell short to get profit. From the backtest, it's obvious that using this trading model can give us portfolio return during the trading
period. Therefore, classic FX model is useful in arbitrage.

### 5.2 Recommendation

Because the definition of carry style is getting return of assets obtained from holding, trading activities in carry style require little about analysis of price tendency using programming. In this way, carry is not as complex as momentum or value analysis, and under this style, the trading activities ask for less time so we think it would be popular in Chinese market. Firstly, we recommend spot holding model to be applied to Chinese market because the mechanism of operating is easy to understand and the data used for calculation in the formula can be easily found. The trading activities under the guidance of spot holding model do not require high funds and the risk in short term is always low, so the model is suitable for new hands or undergraduates. Secondly, about convenience yield model, we do not recommend it to Chinese market because in this model, some factors are highly changeable. For instance, rate of storage cost for commodities is uncertain among different seasons and at the same time, according to the formula $\mathrm{C}=\mathrm{r}+\mathrm{s}-\mathrm{y}$, y is changeable too, so the model is too basic and hard for people to evaluate the future price accurately. Maybe we're supposed to improve the model by turn the factors inside to relatively stable factors rather than directly using it in markets. Thirdly, the collar option model can be used in the Chinese market, for
example, PetroChina makes use of the international financial market to hedge the risk of raw material and product price fluctuations through hedging transactions. But on the other hand, we should fully understand the importance of risk management and respect market rules. You can't just regulate the price of oil going up, there's no hedge against the price going down.
