ABSTRACT

The application of matrices to cryptographic problems, especially with Hill Cipher algorithm, needs an invertible matrix as a key and a plaintext’s diffuser. One of the invertible matrices is a Hadamard matrix (H). The Hadamard matrix is applied to cryptographic problems with Hill Cipher algorithm by modifying encryption and decryption processes with the help of Hadamard matrix properties and modulo operation. The Hill Cipher algorithm requires two keys, namely public and private keys. By using the Hadamard matrix as a public key, the encryption process can be shortened by eliminating the process of checking of the reverse key matrix. Any character can also be used as a private key provided the number of characters doesn’t exceed the square of the Hadamard matrix order.

Keywords: Hadamard matrix, encryption, decryption, Hill Cipher

1. INTRODUCTION

Matrices can be applied in the cryptographic problems. One of the cryptographic algorithms that uses a matrix is the Hill Cipher algorithm. This algorithm uses the matrix as a key to transform plaintext into ciphertext at an encryption process. Then, in the decryption process, ciphertext is multiplied by the inverse of the key matrix to return it to plaintext [1]. This means that the matrix is used as a key and diffuser in the Hill Cipher. The condition for a matrix used in this algorithm is that it must have an inverse under multiplication operation.

One of matrices that has an inverse is the Hadamard matrix. This matrix is a square matrix whose entries are either +1 or −1 and whose rows are mutually orthogonal [2],[3]. The absolute value of the determinant of the matrix is nⁿ/² where n is the order of the matrix [4]. Since the Hadamard matrix is an invertible matrix, it can be used as a key matrix in the Hill Cipher algorithm.

The modification of the Hill Cipher algorithm using the Hadamard matrix makes the algorithm more complex [5]. However, the Hill Cipher algorithm still can be destroyed through cryptanalysis such as brute force attack, plaintext attack, and ciphertext attack [6]. Therefore, the authors modify the Hill Cipher algorithm by employing modulo operation and the properties of the Hadamard matrix. This modification makes the encryption and decryption processes require two keys, namely the public and private key. The public key in this modification uses the Hadamard matrix. Thus the computer program associated with the algorithm can be shortened since the process to check the invertibility of the public key matrix is not required. Besides, any character can be input as a private key. This makes the algorithm even more difficult to destroy.

2. RESULTS AND DISCUSSION

The encryption process makes plaintext in the form of characters as input and produces ciphertext in the form of characters as output. The decryption process is the opposite of the encryption process. Both processes require the American Standard Code of Information Interchange (ASCII) to convert characters to decimal code and vice versa. The ASCII codes are limited, there are only 256 characters. Thus, the encryption process is modified as follows:

\[ C = (H \cdot P) + (K \cdot e) \mod m \]

\[
\begin{pmatrix}
C_1 \\
\vdots \\
C_n
\end{pmatrix} =
\begin{pmatrix}
h_{11} & \ldots & h_{1n} \\
\vdots & \ddots & \vdots \\
h_{n1} & \ldots & h_{nn}
\end{pmatrix}
\begin{pmatrix}
p_1 \\
\vdots \\
p_n
\end{pmatrix} +
\begin{pmatrix}
k_{11} & \ldots & k_{1n} \\
\vdots & \ddots & \vdots \\
k_{n1} & \ldots & k_{nn}
\end{pmatrix}
\begin{pmatrix}
e_1 \\
\vdots \\
e_n
\end{pmatrix} \mod m. \quad (1)
\]

Through the definition of the Hadamard matrix, the inverse of the matrix is known as \( \frac{1}{n} H_n^T \), so that the decryption process is expressed as
The following is an encryption process using a Hadamard matrix of order 2×2 as a public key and 255 symbolized by gcd(4,255) can be written as gcd(255, 4). Then, using Euclid’s algorithm, we get

\[ 255 = 127 \cdot 2 + 1, \]
\[ 2 = 2 \cdot 1 + 0. \]

It means that gcd(2, 255) = gcd(255, 1) = 1. Therefore, 4 and 255 are relatively prime. The modified Hill Chiper algorithm can be used.

2.1.2. Representing the Private Key as a 2×2 Matrix

The number of characters in the private key is 4, so that the number of entries in the matrix of order 2×2 is 4. Then, the private key is represented as the matrix

\[ \begin{pmatrix} m & t \\ k & 2 \end{pmatrix}. \]

2.1.3. Converting Every Character in the Private Key to be a Decimal Number

Each character is converted to be decimal number, so that we get

\[ \begin{pmatrix} 109 & 116 \\ 107 & 50 \end{pmatrix}. \]

2.1.4. Splitting the Plaintext into 2×1 Blocks

Each block consists of 2 characters since the Hadamard matrix used is a matrix of order 2×2. Then, the obtained matrices \( P_1, P_2, P_3, P_4, P_5, P_6, P_7 \) and \( P_8 \) are

\[ \begin{pmatrix} \text{M} & \text{t} \\ \text{n} & \text{a} \end{pmatrix}, \begin{pmatrix} \text{m} & \text{t} \\ \text{a} & \text{a} \end{pmatrix}, \begin{pmatrix} \text{k} & \text{t} \\ \text{a} & \text{a} \end{pmatrix}, \begin{pmatrix} \text{n} & \text{t} \\ \text{a} & \text{a} \end{pmatrix}, \begin{pmatrix} \text{Space} & \text{t} \\ \text{a} & \text{a} \end{pmatrix}, \begin{pmatrix} \text{d} & \text{t} \\ \text{a} & \text{a} \end{pmatrix}, \begin{pmatrix} \text{Space} & \text{t} \\ \text{a} & \text{a} \end{pmatrix}, \begin{pmatrix} \text{Space} & \text{t} \\ \text{a} & \text{a} \end{pmatrix}. \]

respectively. The number of characters in “Matematika Unsoed” is 17. Consequently, when they are divided into 2×1 blocks, there are 9 blocks with 1 incomplete block. Here, incomplete blocks are filled with “space” as dummy characters.

2.1.5. Converting Every Character in Plaintext to be a Decimal Number

Each character is converted to be a decimal number. Then, we get
\[(77, 116, 109, 107, 32, 110, 111, 101) \text{ and } (100, 32)\].

### 2.1.6. Encrypting Each Plaintext Block One by One

The encryption is done through the following calculation.

\[
\begin{align*}
C_1 &= ([H_2 \cdot P_1] + (K \cdot e_2)) \mod 255 = (144, 137) \\
C_2 &= ([H_2 \cdot P_2] + (K \cdot e_2)) \mod 255 = (187, 172) \\
C_3 &= ([H_2 \cdot P_3] + (K \cdot e_2)) \mod 255 = (176, 169) \\
C_4 &= ([H_2 \cdot P_4] + (K \cdot e_2)) \mod 255 = (191, 168) \\
C_5 &= ([H_2 \cdot P_5] + (K \cdot e_2)) \mod 255 = (174, 167) \\
C_6 &= ([H_2 \cdot P_6] + (K \cdot e_2)) \mod 255 = (87, 104) \\
C_7 &= ([H_2 \cdot P_7] + (K \cdot e_2)) \mod 255 = (195, 152) \\
C_8 &= ([H_2 \cdot P_8] + (K \cdot e_2)) \mod 255 = (182, 167) \\
C_9 &= ([H_2 \cdot P_9] + (K \cdot e_2)) \mod 255 = (102, 225)
\end{align*}
\]

That calculation obtained ciphertext block \(C_1, C_2, C_3, C_4, C_5, C_6, C_7, C_8,\) and \(C_9,\) namely

\[
\begin{align*}
(144, 137), (187, 172), (176, 169), (191, 168), (174, 167), (87, 104), \\
(195, 152), (182, 167), (102, 225)
\end{align*}
\]

respectively.

### 2.1.7. Converting Each Number in the Ciphertext Matrices to be Characters

Each number in \(C_1, C_2, C_3, C_4, C_5, C_6, C_7, C_8,\) and \(C_9,\) is converted to a character. Then, the ciphertext block becomes

\[
\begin{align*}
(‘m’), (‘a’), (‘t’), (‘e’), (‘ ’), (‘ ’), (‘H’), (‘A’), (‘t’)
\end{align*}
\]

Thus, we get the ciphertext “Matematika Unsoed” as the result of encryption of “Matematika Unsoed”.

The encryption process using Matlab is done as shown in the Figure 1.

![Figure 1 Encryption process using Matlab](image)

The program instructs to input the encrypted plaintext. Then, by inputting “Matematika Unsoed”, the program is ordered to input the order of the Hadamard matrix, the private key, and the modulo operation and the Hadamard matrix used. The user input 2 as the order of the matrix, “mtk2” as the private key, and 255 as the modulo operation number. The user also inputs

\[
\begin{pmatrix}
1 & 1 \\
1 & -1
\end{pmatrix}
\]

as the Hadamard matrix used. Then, the program displays

“\%o”®©©®§WhÃ¨§fá”

Thus, we get the ciphertext “\%o”®©©®§WhÃ¨§fá” from plaintext “Matematika Unsoed”.

### 2.2. Decryption on the Hill Cipher Algorithm Using the Hadamard Matrix

The following is a decryption process using a Hadamard matrix of order 2x2 as a public key and 255 characters in ASCII code. For example, given ciphertext

“\%o”®©©®§WhÃ¨§fá”

with

“mtk2”

is as the private key and

\[
H_2 = \begin{pmatrix}
1 & 1 \\
1 & -1
\end{pmatrix}
\]

is as the Hadamard matrix used. The decryption process is carried out in the following way.

#### 2.2.1. Representing the Private Key as a 2x2 Matrix

The private key is represented by the matrix

\[
\begin{pmatrix}
1 & 1 \\
1 & -1
\end{pmatrix}
\]
\[ \binom{m}{k} \tbinom{t}{2}. \]

2.2.2. Converting Every Character in the Private Key to be a Decimal Number

Each character is converted to a decimal number, so that we get
\[ \frac{109}{107} \frac{116}{50}. \]

2.2.3. Finding the Inverse of the \( H_2 \mod 255 \) Matrix

Based on equation (2), the inverse of \( H_2 \mod 255 \) can be expressed as
\[ H_2^{-1} \mod 255 = \frac{1}{2}(H_2^T) \mod 255 = 2^{-1}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \mod 255. \quad (3) \]

In the encryption process, 2 and 255 are relatively prime so that the inverse of \( 2 \mod 255 \) exists. To find the inverse of \( 2 \mod 255, \gcd(2, 255) = 1 \) is in a linear combination using Euclid’s algorithm, namely
\[ 1 = 255 \cdot (1) - (127) \cdot (2) \]
\[ = (255) \cdot (1) + (2) \cdot (-127). \]

We get 1 mod 255 = 2 (−127) + 255 (1) mod 255. This shows that 1 mod 255 = 2 (−127) mod 255. Therefore, the inverse of 2 mod 255 is −127. Thus, the inverse of the Hadamard matrix can be expressed as
\[ \frac{1}{2}(H_2^T) \mod 255 = (-127) \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \mod 255 \]
\[ = (-127 \mod 127) \begin{pmatrix} 1 & -1 \\ 1 & 127 \end{pmatrix} \]
\[ = \begin{pmatrix} 128 & 128 \\ 128 & 127 \end{pmatrix}. \]

2.2.4. Splitting Chipertext into 2 \( \times \) 1 Blocks

The Chipertext is respectively grouped into matrices \( C_1, C_2, C_3, C_4, C_5, C_6, C_7, C_8 \), and \( C_9 \), namely
\[ \begin{pmatrix} 144 \cr 137 \end{pmatrix}, \begin{pmatrix} 187 \cr 172 \end{pmatrix}, \begin{pmatrix} 176 \cr 169 \end{pmatrix}, \begin{pmatrix} 191 \cr 168 \end{pmatrix}, \begin{pmatrix} 174 \cr 167 \end{pmatrix}, \begin{pmatrix} 87 \cr 104 \end{pmatrix}, \begin{pmatrix} 195 \cr 152 \end{pmatrix}, \begin{pmatrix} 182 \cr 167 \end{pmatrix}, \text{and} \begin{pmatrix} 102 \cr 125 \end{pmatrix}. \]

2.2.6. Decrypting Each Plaintext Block One by One

The decryption is done through the following calculation.
\[ P_1 = \binom{1}{2} \binom{H_2}{r}(C_i - (K \cdot e_i)) \mod 255 = \begin{pmatrix} 97 \\ 77 \end{pmatrix}, \]
\[ P_2 = \binom{1}{2} \binom{H_2}{r}(C_i - (K \cdot e_i)) \mod 255 = \begin{pmatrix} 116 \\ 101 \end{pmatrix}, \]
\[ P_3 = \binom{1}{2} \binom{H_2}{r}(C_i - (K \cdot e_i)) \mod 255 = \begin{pmatrix} 109 \\ 97 \end{pmatrix}, \]
\[ P_4 = \binom{1}{2} \binom{H_2}{r}(C_i - (K \cdot e_i)) \mod 255 = \begin{pmatrix} 116 \\ 105 \end{pmatrix}, \]
\[ P_5 = \binom{1}{2} \binom{H_2}{r}(C_i - (K \cdot e_i)) \mod 255 = \begin{pmatrix} 107 \\ 97 \end{pmatrix}, \]
\[ P_6 = \binom{1}{2} \binom{H_2}{r}(C_i - (K \cdot e_i)) \mod 255 = \begin{pmatrix} 32 \\ 85 \end{pmatrix}, \]
\[ P_7 = \binom{1}{2} \binom{H_2}{r}(C_i - (K \cdot e_i)) \mod 255 = \begin{pmatrix} 110 \\ 115 \end{pmatrix}, \]
\[ P_8 = \binom{1}{2} \binom{H_2}{r}(C_i - (K \cdot e_i)) \mod 255 = \begin{pmatrix} 111 \\ 101 \end{pmatrix}, \]
\[ P_9 = \binom{1}{2} \binom{H_2}{r}(C_i - (K \cdot e_i)) \mod 255 = \begin{pmatrix} 100 \\ 32 \end{pmatrix}. \]

The plaintext blocks \( P_1, P_2, P_3, P_4, P_5, P_6, P_7, P_8, \) and \( P_9 \) are obtained, namely
\[ \begin{pmatrix} 77 \\ 97 \end{pmatrix}, \begin{pmatrix} 116 \\ 101 \end{pmatrix}, \begin{pmatrix} 109 \\ 97 \end{pmatrix}, \begin{pmatrix} 116 \\ 105 \end{pmatrix}, \begin{pmatrix} 107 \\ 97 \end{pmatrix}, \begin{pmatrix} 32 \\ 85 \end{pmatrix}, \begin{pmatrix} 110 \\ 115 \end{pmatrix}, \begin{pmatrix} 111 \\ 101 \end{pmatrix}, \text{and} \begin{pmatrix} 100 \\ 32 \end{pmatrix} \]

respectively.

2.2.7. Converts Each Number in the Matrix to Characters

Each number in \( P_1, P_2, P_3, P_4, P_5, P_6, P_7, P_8, \) and \( P_9 \) is converted to be characters, so that the plaintext blocks \( P_1, P_2, P_3, P_4, P_5, P_6, P_7, P_8, \) and \( P_9 \) become
\[ \begin{pmatrix} M_a \cr \text{Space} \end{pmatrix}, \begin{pmatrix} m_a \cr i \end{pmatrix}, \begin{pmatrix} k_a \cr \text{Space} \end{pmatrix}, \begin{pmatrix} n_s \cr \text{Space} \end{pmatrix}, \begin{pmatrix} o \cr \text{Space} \end{pmatrix}, \begin{pmatrix} d \cr \text{Space} \end{pmatrix}. \]

respectively. Thus, the plaintext “Matematika Unsoed” is obtained as the result of the decryption of
The decryption using Matlab is carried out as shown in the Figure 2.

```
>> Decrypt
INPUT YOUR TEXT PLEASE : %»¬°©¿¨®§WhÅ¥§fá
THE ORDER OF MATRIX : 2
THE MODULO OPERATION : 255
INPUT THE PRIVATE KEY : mtk2
ans =
Matematika Unsoed
```

Figure 2 Decryption Process using Matlab

The program instructs to input the decrypted ciphertext. Then, by inputting “%»¬°©¿¨®§WhÅ¥§fá”, the program is ordered to input the order of the matrix, the private key, the modulo operation, and the Hadamard matrix used. The user input 2 as the order of the matrix, “mtk2” as the private key, and 255 as the modulo operation number. The user also input

\[
\begin{pmatrix}
1 & 1 \\
1 & -1
\end{pmatrix}
\]

as the Hadamard matrix used. Then, the program displays “Matematika Unsoed”. Thus, we get the plaintext “Matematika Unsoed” from ciphertext “%»¬°©¿¨®§WhÅ¥§fá”.

3. CONCLUSION

The encryption-decryption process of the Hill Chiper algorithm is simpler by using the Hadamard matrix as a public key because of the invertibility of the matrix.

The computation of the encryption-decryption process using the computer program gives the same results as that using manual computation. It means that the computer program gives accurate results.

The computer program can’t compute the empty space that’s symbolized by the ASCII code of 0. In other side, the ASCII code of number 1 – 31 can’t be printed as a character. Thus, for future works, the number of 32 has to be added as a base number for every ciphertext or plaintext that’s obtained through the encryption or the decryption process.

AUTHORS’ CONTRIBUTIONS

The first author, SAF CONCEIVED of the presented ideas and DEVELOPED the hadamard matrix and the Hill Chiper theory. SAF also DESIGNED the computational solution of cryptographic problem using Hill Chiper algorithm and performed the computations. The second, MM, and the third author, BHG, VERIFIED the analytical method and ENCOURAGED the first author to investigate the Hadamard matrix role in the encryption and the decryption process. In other side, MM and BHG GUIDED and PROVIDED suggestions for each stage of research. All authors discussed the results and contributed to the final version.
