# Trip Generation and Trip Distribution Analysis of Commuter Line 

Ega Cahyani Putri ${ }^{1(\boxtimes)}$, Nanda Ahda Imron ${ }^{1}$, and Nanda Sani Mitra Imron ${ }^{2}$<br>${ }^{1}$ Indonesian Railway Polytechnic, Tirta Raya Street, Manguharjo, Madiun 63161, Indonesia ega.mtp1911@taruna.ppi.ac.id<br>$2^{2}$ PT. Kereta Api Indonesia (KAI), Jl. Perintis Kemerdekaan No. 1 Kec. Sumur Bandung Jawa Barat, Babakan Ciamis, Kota Bandung 40117, Indonesia

#### Abstract

Greater Bandung Commuter line (CL) is expected to operate after the double-track construction and electrification in Padalarang-Cicalengka route in 2024 is completed. Among the route, there is Gedebage Station, classified as "operational station" (with no passenger that board or alight from), in which its function will be enhanced as passenger station. In order to meet the public's need of transport service, it is important to analyse the trip generation and trip distribution. In March 2022, home interview survey was conducted in residential area near Gedebage Station to obtain the origin-destination data and combined with origin-destination data of the existing trains. ARIMA method is carried out to forecast trip generation, as Fratar method is to analyze its trip distribution. The study concludes, the best model for forecasting is AR (1) with biggest R-square value, altogether with smallest Aikake Information Criterion (AIC) and Schwarz Criterion (SC). The highest trip distribution obtained is trip from Bandung Station to Cicalengka Station.

Keywords: Trip Generation • Trip Distribution • ARIMA • Fratar

## 1 Introduction

The constant needs of transportation will be increasing transportation users and be raising congestion [1]. As an alternative to solve traffic problems, CL is going to be operated in Bandung area, referring to Indonesia Railway Masterplan (RIPNas) 2030 in the matter of Double-Track Construction and Electrification in the route of Padalarang-BandungCicalengka [2] that is expected to complete by the year 2024.

In the aforementioned route, Gedebage Station as a operational station is going to be revitalized into a modern passenger station [2]. So that the transportation service be able to fulfill community needs, it is important to obtained forecast on the sum of trip generation and its trip distribution.

## 2 Research Method

Trip data is collected from data recorded by the Operation Area (DAOP) II Bandung, combined with the results of home interview survey in the area of Gedebage Station,

Fig. 1. CL Route Padalarang-Cicalengka
within 500 m radius. It is considered so as Gedebage Station is designated, in the spatial planning, as a centralized area for integrated intermodal, covering in range of 400-800 m from the mass transportation transit node [3]. In home interview survey, the number of populations is calculated through manual count on the roof number in Google Earth Pro apps and it resulted a total of 1.520 houses. Using purposive sampling, the obtained sample is 210 respondents. The indicators used during the interview including the number of the family member(s), vehicle ownership, family identity, and the family member(s)' trip. From DAOP II, the data obtained including passengers' trip (origin) who accessed Padalarang-Cicalengka route train during January 2019-March 2022.

Interview instrument is analyzed using Lawshe's Content Validity Ratio (CVR) that has been used to examine contents' validity [3]. Each respondent answered questions for every item with three answer options, namely (1) necessary, (2) less necessary, and (3) unnecessary [4]. CVR is calculated with this following formula [3]:

$$
\begin{equation*}
\mathrm{CVR}=\frac{\left(n_{e}-\frac{N}{2}\right)}{\frac{N}{2}} \tag{1}
\end{equation*}
$$

## CVR: Content Validity Ratio

$n_{e}$ : The number of respondents indicating an item as necessary
N : The total number of respondents
The data obtained from the survey then accumulated with the trip generation data from DAOP II, to be analyzed using ARIMA method through EViews software. ARIMA model calculates AR (autoregressive) and MA (moving average), with I (integrated) that is either stationary or differential. ARIMA model using order $p$ to indicate the value of AR, order $d$ to indicate the differential leveling, and order $q$ to indicate the value of MA [6].

1. Autoregressive AR ( $p$ ) model

$$
\begin{equation*}
X_{t}=\mu^{\prime}+\emptyset_{1} X_{t-1}+\emptyset_{2} X_{t-2}+\ldots+\emptyset p X_{t-p}+e_{t} \tag{2}
\end{equation*}
$$

$\mu^{\prime}$ : A constant.
$\emptyset_{p}$ : Autoregressive parameter at $p$.
$X_{t-1}$ : Error value at $t$.
$X_{t}$ : General average.
2. Moving Average MA (q) model

$$
\begin{equation*}
X_{t}=\grave{\mathrm{l}}+e_{t}-\grave{\mathrm{e}}_{1} e_{t-1}-\grave{\mathrm{e}}_{2} e_{t-2}-\cdots .+\grave{\mathrm{e}}_{p} e_{t-k} \tag{3}
\end{equation*}
$$

ì: Constant.
$\grave{\mathrm{e}}_{1}-\grave{\mathrm{e}}_{1}$ : Moving average parameter.
$e_{t-k}$ : Error value at $t-k$.
$X_{t}$ : General average.
3. Autoregressive moving average ARMA $(p, q)$ model

$$
\begin{align*}
& X_{t}=\grave{\mathrm{\imath}}+\emptyset_{1} X_{t-1}+\emptyset_{2} X_{t-2}+\cdots+\emptyset p X_{t-p}+e_{t}+\grave{\mathrm{e}}_{1} e_{t-1}-  \tag{4}\\
& \grave{\mathrm{e}}_{2} e_{t-2}-\cdots .+\grave{\mathrm{e}}_{q} e_{t-q}
\end{align*}
$$

$X_{t}$ : General average.
$\emptyset p$ : Autoregressive parameter at $p$.
$\grave{e ̀}_{q}$ : Autoregressive parameter at $q$.
$e_{t}$ : Error value given at $t$.
$e_{t-q}$ : Error value given at $t-k$.
ì A constant.
After trip generation value on the planned year generated, the trip distribution then analyzed through Fratar method. The Fratar method is analyzed using repetition process or iteration using this following equation [7].

$$
\begin{equation*}
\mathrm{Ti}-\mathrm{j}=\frac{T i(G) . t i-j \cdot E j}{t i-j \cdot E j+t i-k E k+\ldots+t i-n E n} \tag{5}
\end{equation*}
$$

$\mathrm{Ti}-\mathrm{j}$ : Trip generation forecast from $\mathbf{i}$ to $\mathbf{j}$.
$T i(G)$ : The sum of trip in the target year.
$t i-j \ldots t i-k \ldots t i-n$ : The sum of trip in the current period from the origin to destination zone.
$E j \ldots E k \ldots$. . . $n$ : Growth factor.

### 2.1 Home Interview

Following interview to the community lived near Gedebage Station, it is identified that the average number of family members is 3,6 per family, $54 \%$ of the respondents are male and the $46 \%$ other are female, and social activity became the dominant reason to take a train trip. Data of trip destination collected from the interview was daily sample data (trip/day), thus it has to be multiplied with expansion factor (FE) to convert it into daily population data (trip/day). Expansion factor is calculated using this following formula [8]:

$$
\begin{align*}
& F E=\frac{\left\{A-\frac{A}{B} *(C+D)\right\}}{B-C-D} \\
& F E=\frac{\left\{1520-\frac{1520}{210} x(1520-210)+0\right\}}{210-(1520-210)-0}=7,238095238 \tag{6}
\end{align*}
$$

A refers to the sum of all buildings or families, $B$ refers to the number of buildings chosen as sample, C refers to the remaining buildings that are not included as sample, and D refers to the number of buildings that were empty and did not respond or refused being sample. Daily population data (trip/day) then is converted into monthly population data (trip/month) and is resulted in 638,617 trip for its total trip generation.

## 3 Trip Generation Forecasting Using ARIMA Method

Trip generation forecasting of Greater Bandung CL passengers using time series data of trip during Januari 2019 - March 2022 (as collected from DAOP II) that is deriving out of combined origin-destination (O/D) matrix from survey result and data collected by DAOP II. It is known that during 2020-2021, the world is facing COVID-19 pandemic and travel restriction was implemented, resulting in the significant decrease on trip. Even in year 2022, travel requirement is still applied. These factors, thus, will affect the result of forecasting.

### 3.1 Stationarity Test

As mentioned in the graph, the data tends to avoid the average value thus it can be concluded that the data has not been stationer. The result on correlogram test and unit root test is shown that the data has also not been stationer to the Level stage, so it demands differencing [5]. On the first stage of correlogram differencing test, cited that the value of Q-Statistic Ljung-Box on the last lag is 16,975 smaller that the chi square $\left(\chi^{2}\right)$ critical value while the df value is 39 in alpha $(\alpha) 5 \%$ that is 54.572 ; thus, the data in the first phase differential is considered stationer.

On the unit root test developed by Dicky-Fuller, it has $\mathrm{H}_{1}$ hypothesis that if Itcount $|>| t$-tablel meaning the data is stationer, while $\mathrm{H}_{0} \mid t$-count $|<| t$-tablel meaning the data has not been stationer [9].

The value of Augmented Dickey-Fuller (ADF) is absolute, $t$-statistic value in4.679782 is bigger than value shown in each $t$-table that reached -3.621023 ( $1 \%$ level), -2.943427 ( $5 \%$ level), and -2.610263 ( $10 \%$ level). It is concluded that the data has been stationer in the first stage of the different [9].

### 3.2 Determining the Model

There are several methods to achieve ARIMA parameters, including the following:

1. The order chosen based on the highest value and $d$ value refers to its differential stage [5].
2. Looking to the ACF and PACF pattern that reached the lag peak and $d$ value is in accordance with the differential stage [10].
3. Trial and error, by testing a number of different values then choosing one value (or several values) that will be minimizing the sum of square residual [11].
4. Looking at the ACF and PACF pattern to find out the tally on correlogram that is cut off or is out of the bartlett, with $d$ value that is in accordance with the differential stage.

Fig. 2. Trip generation pattern (monthly)

By applying the four aforementioned methods, the best model is acquired through trial and error method. The most suitable method is chosen by considering the probability value that is smaller than alpha ( $\alpha$ ) $5 \%$ and based on goodness of fit of each parameter. Goodness of fit has several criteria; those are the biggest R-square value and the smallest value of Akaike Information Criterion (AIC) and Schwarz Criterion (SC) [5].

Table 3. First stage of ADF Test

|  |  | t-Statistic | Prob.* |
| :--- | :--- | :--- | :--- |
| Augmented Dickey-Fuller test statistic | -1.569750 | 0.4879 |  |
| Test critical values: | $1 \%$ level | -3.615588 |  |
|  | $5 \%$ level | -2.941145 |  |
|  | $10 \%$ level | -2.609066 |  |

* MacKinnon (1996) one-sided p-values.

Table 4. Parameter estimate

| Model | Variable | Coeff. | AIC | SC | $\mathrm{R}^{2}$ | Prob. |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| ARIMA(1,0,0) | C AR(1) | 645069.9 | 26.40444 | 26.53241 | 0.818782 | 0.00130 .0000 |
|  |  | 0.897424 |  |  |  |  |

ARIMA model $(1,0,0)$ or AR (1) is the most suitable model in forecasting trip generation of Greater Bandung CL passengers. AR model (1) is chosen with the following criteria: the biggest R-square value at 0.818782 ; Akaike Information Criterion (AIC) value at 26.40444 and Schwarz Criterion (SC) value at 26.53241 , which are the smallest amongst the other model.

### 3.3 Diagnostic Test/Model Evaluation

The test on diagnose residual is held to examine whether the estimated residual result has been qualified as white noise or random, by analyzing its residual value through correlogram ACF and PACF [5]. This following table displays the result of residual model test.

During the last lag, the value of Q-Statistic Ljung-Box shown at 14.167 , that is smaller than the critical value of chi square $\left(\chi^{2}\right)$ with df at 39 in alpha ( $\alpha$ ) $5 \%$ that is given at 54.572. This means, the residual value estimated has been qualified as white noise or random; thus, the model is considered good [5].

Table 5. Diagnostic test

### 3.4 Forecasting

In the following step, the forecasting is done using EViews 9.0 software for the period when Greater Bandung CL will be operating on December 2024, that is given at 645,187 trips and forecasting for the following five-years period or up to December 2027 at 645,072 trips. The forecasting results are displayed in the following tables. The decrease of trip generation on December 2027 period happens, since the trip data that shown significant decrease during pandemic as a consequence of the travel restriction.

## 4 Trip Distribution Analysis Using Fratar Method

After the value of production trip in a month period obtained, then the distribution of passengers' trip for Padalarang-Cicalengka route is calculated using Fratar method [7]. The growth level must be achieved at $\mathrm{Ei}=1$ through iteration so that the analysis is considered as complete [13].

The trip distribution for December 2024 period, when the CL is expected to be operated, the value of Ei has not reached 1 ; thus, iteration is applied in order to reach Ei value at 1.00 . Ei value reached 1 during the 38th iteration, meanwhile the highest trip distribution from Bandung Station to Cicalengka Station is at 38,895 trips.

The trip distribution for CL passengers for the next five-years period or up to December 2027 is also calculated. For the aforementioned condition, the Ei value has not reached 1 , so that iteration is needed. Ei reached 1 on its 37 th iteration and the highest trip distribution from Bandung Station to Cicalengka Station is at 38,888 trips.

## 5 Conclusion

1. Based on the prior time series data, this study concluded that ARIMA model $(1,0,0)$ or AR (1) is the best model to forecast trip generation CL passengers' for PadalarangCicalengka route in the future
2. The number of trip generation for December 2024, when CL will be operated, is at 645,187 trips in a month, while the number of trip generation for December 2027 is at 645,072 trips in a month.
3. In December 2024, the highest trip distribution from Bandung Station to Cicalengka Station is 38,895 trips. Meanwhile, for December 2027, the highest trip distribution from Bandung Station to Cicalengka Station is at 38,895 trips.
