**Abstract.** With population growth which increases every year, it will also be accompanied by a reduction in natural resources and energy. These natural resources are in the form of food needs. With the increasing demand for food and energy needs, there must also be the development of technology in the field of electricity generation. One of them is the development of the agrivoltaic system. Agrivoltaic is a concept that combines land use with the generation of electrical energy needs. The purpose of this study is to find out with data on natural conditions in Central Java whether it can be used for the development of an agrivoltaic system. Researchers have conducted research with plants that are suitable for the agrivoltaic system and based on the available data, these plants are widely planted in Central Java, including: peanuts, tomatoes, and green beans. Data on the amount of land with plants suitable for agrivoltaic development of 4,800 hectares is expected to produce 2,400 MWp of energy. This study concludes that it can provide an overview of the natural conditions of Central Java so that it can be used as a reference for the development of the agrivoltaic system in the future.

Keywords: Growth population · Foof and Energy · Agrivoltaic

### **1** Introduction

From year to year, the population of Central Java has grown every year, increasing by around 4.1 people or an average of 400 thousand, a total of 36.52 million people in September 2020. Based on this, the population of Central Java continues to increase. In a period of ten years, from 2010 to 2020, the population growth rate of Central Java is 1.17 percent per year [1]. There are basic needs that are increasing in demand every day, namely food and energy. Food is a very basic need and energy has also experienced a significant increase. There must be a solution that can secure food and energy growth [2], one of the solutions is agrivoltaic [3, 4]. Agrivoltaic is a concept that combines the use of agricultural land with the production of electricity from a photovoltaic mini-grid. The agrivoltaic system can not only change and preserve agricultural land but can also make crop production more effective and water use more efficient [5].

**Fig. 1.** (a) Solar panels are placed in the vacant land between the plants; (b) Solar panels are placed on top of the greenhouse media; (c) Solar panels are placed in a frame placed on top of the plant [6].

Agrivoltaic itself has three development patterns, namely the initial concept of agrivoltaic solar panels placed in empty rows on agricultural land (Figure a). The second concept uses a greenhouse structure, which is added to the top by solar panels at a certain distance (Figure b). The third concept is to build a panel structure on top of the plant by adding a framework (Figure c) [6]. Agrivoltaic systems are very effective in maximizing land production, especially when compared to renewable energy generation systems where solar panels are only installed on the ground or on the roof [7] (Fig. 1).

Central Java Province has an area of  $\pm$  1,684,746.24 hectares of agricultural land. The agricultural land is planted with many agricultural products, but only a few crops can be applied with agrivoltaic. These include peanuts [8], green beans [8], and marglope varieties of tomatoes [8, 9]. The amount of land with plants that can be used for agrivoltaic is  $\pm$  166 Ha (166,000,000 m<sup>2</sup>). If all agricultural land is installed agrivoltaic, it can have a significant impact by generating  $\pm$  83 MWp of electricity. The amount of electricity can meet the energy needs of  $\pm$  100 thousand customers. The amount of energy of 83 MWp is obtained from the equation:

$$\frac{\text{land area for a grivoltaic system development}}{20.000 \, m^2} = \dots MWp$$

where:

MWp: Mega Wattpeak.

#### 2 Material and Methods

East Java Province in the east, and the Java Sea in the north. Its area is recorded at 32,544.12 hectares or about 25.04% of the island of Java (1.70% of Indonesia's area). The total area consists of  $\pm$  1,684,746.24 Ha (30.80%) in paddy fields, and 2.25 million Ha (69.20%) is non-rice field land. According to the Climatology Station Class 1, Central Java in 2015 the temperature of Central Java was between 23 °C to 28 °C. Where places that are located close to the coast have relatively high average air temperatures and average air humidity varies from 69% to 83% [10].

Agrivoltaic is suitable to be applied to agricultural land with plants that are tolerant of the shadow effects of solar panels. These include lettuce [11], arugula, Asian vegetables, mustard greens, kale, sorrel, spinach, leeks, broccoli, cabbage, peanuts, sweet potatoes, taro, cassava, and sweet potatoes. Or plants that only need a little sun, such as lettuce [11], cucumbers, radishes, pumpkins, cabbage, and green peppers. In the Central Java region, of course, not all of these plants are not planted, for plants that are in the Central Java region and are suitable for agrivoltaic with a given shade, such as peanuts [8], green beans [8], tomatoes of marglope varieties [8, 9].

Data collection was taken from some technical data at the Central Java Provincial Statistics Agency and also some data taken from the Retscreen application including air temperature, humidity, rainfall, daily solar radiation, atmospheric pressure, wind speed, earth temperature, degrees of heating per day and cooling temperature per day (Table 1).

The data graph below shows the amount of daily solar radiation horizontally in  $kWh/m^2/s$ . From March to October, there were many increases, and the peak was in September at 6.80 kWh/m<sup>2</sup>/d (Fig. 2).

Then the amount of radiation in the Central Java region is shown in Fig. 3 and Fig. 4. Figure 4 states that the highest radiation is on the northern coast of Java from the city of Tegal to the city of Rembang which ranges from 1600–1700. Then for Semarang, Salatiga and Surakarta also have high radiation intensity, which is between 1700–1800.

Mount	Air tempera ture	Reactive humidity	Rainfall	Daily solar radiation – horizontal	Atmos pheric pressure	wind speed	Earth tempera ture	Degrees – days 18 °C	Cooling tempera ture – days 10 °C

Table 1. The data on natural conditions in Central Java with the RETSCREEN application

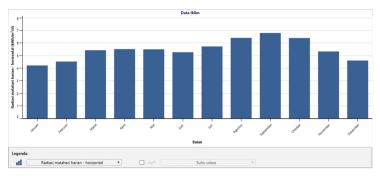

Fig. 2. Daily solar radiation horizontally in kWh/m<sup>2</sup>/s

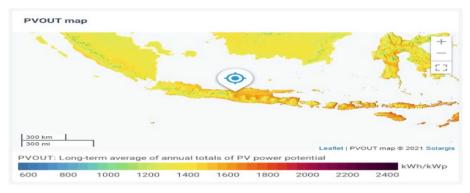

Fig. 3. Daily solar radiation in the territory of Indonesia

Fig. 4. Daily solar radiation in Central Java region

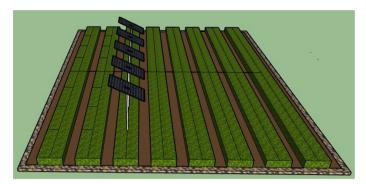

Fig. 5. System agrivoltaic development in agricultural land

The development method from the initial agrivoltaic concept that is suitable for areas in Central Java and does not interfere much with the activities of farmers in land management is the concept of solar panels placed between plants on each mound. That way, agricultural equipment, and crop irrigation systems will not be disturbed by the development of this agrivoltaic system (Fig. 5).

Then with the daily solar radiation data in areas in Central Java, this data can be used as a reference for areas that have the potential for agrivoltaic development, namely in Semarang District, Kendal District, Batang District, Pekalongan District, Pemalang District, and Tegal District.

#### **3** Result and Discussion

Agrivoltaic is suitable to be applied to agricultural land with plants that are tolerant of the shadow effects of solar panels. These include lettuce [8], arugula, Asian vegetables, chard, mustard greens, kale, sorrel, spinach, leeks, broccoli, cabbage, peanuts, sweet potatoes, taro, cassava, and sweet potatoes. Or plants that only need a little sunlight, such as cucumbers, radishes, pumpkins, cabbage, and green peppers. In the Central Java region, of course, not all of these plants are not planted, for plants in the Central Java region such as peanuts [8], green beans [8], and tomatoes of marglope varieties [8, 9] (Fig. 6).

By observing and analyzing data on harvested area, crop productivity the energy potential in all districts in Central Java, especially in the districts of Semarang, Kendal, Batang, Pekalongan, Pemalang, Tegal, it can be concluded that there is potential for the use and development of agrivoltaic systems (Table 2).

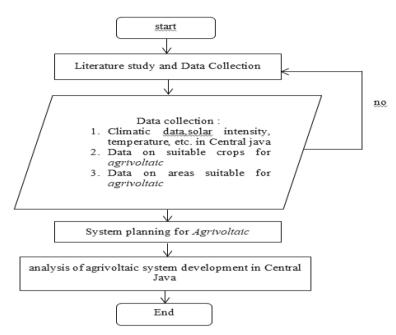

Fig. 6. The flowchart of analysis of agrivoltaic systems development in Central Java

The potential of agrivoltaic in Indonesia, especially in Central Java, is very wide open. Because in Central Java, many plants are suitable for shade, namely the placement of solar panels. Then the next factor is that the Central Java area has a lot of sunlight intensity, and the Central Java region still relies on fossil fuels for power generation.

Then the intensity of these cities ranges from 1500–1700 kWh/kWp. The potential development of the agrivoltaic system itself totals 83 MWp. Of the 83 MWp obtained 29 MWp was from land with peanut plants, then 52 MWp obtained from mung bean fields and 2.5 MWp obtained from tomato fields. Then for the area with the most agricultural land, Semarang district with a land area of 1,999 ha and can produce power of approximately 1,000 MWp.

Number	City	Plants						
		Peanuts		Tomatoes

## 4 Conclusion

With several criteria and the suitability of existing natural conditions, all regions in Central Java and in particular, namely Semarang Regency, Batang Regency, Kendal Regency, Pekalongan Regency, Pemalang Regency and Tegal Regency have enormous potential to be used as agrivoltaic land.
