# Hexavalent Half-arc-transitive $G$ aphs of $O$ der 6p 

Xiuyun Wang<br>School of Mathematic Science<br>University of Jinan<br>Jinan, Shandong, China<br>1519168700@qq.com

#### Abstract

A graph is half-arc-transitive if its auto orphism group acts transitively on its vertex set and edge set, but not arc set. Y-Q. Feng et al. gave the classification of tetravalent half-arc-transitive graph of order $6 p$. In this paper, we proved that hexavalent half-arc-transitive graph of order 6 phas order 42.

Keywords- Cayley graph; half-arc-transitive graph; transitive graph; Heawood graph; quotient graph

## I. InTRODUCTION

Throughout this paper graphs are assumed to be finite, simple and undirected, but with an implicit orientation of the edges when appropriate. For a graph X , let $\mathrm{V}(\mathrm{X})$, $\mathrm{E}(\mathrm{X}), \mathrm{A}(\mathrm{X})$ and $\operatorname{Aut}(\mathrm{X})$ be the vertex set, the edge set, the arc set and the auto orphism group of X , respectively. Let $D_{2 n}$ be the dihedral group of order $2 n$, and $Z_{n}$ the cyclic group of order $n$ as well as the ring of integers modulo $n$. Denote by $\mathbb{Z}_{n}^{*}$ the multiplicative group of $Z_{n}$ consisting of numbers coprime to $n$, and for a prime p , denote by $\mathbb{Z}_{p}^{n z}$ the elementary abelian group $Z_{p} \times Z_{p}$ $\times \cdots \times Z_{p}$ (m times). For a finite group $G$ and a subset $S$ of G such that $1 \notin S$ and $S=S^{-1}$, the Cayley graph Cay $(G, S)$ on $G$ with respect to $S$ is defined to have vertex set $G$ and edge set $\{\{\mathrm{g}, \mathrm{sg}\} \mid \mathrm{g} \in \mathrm{G}, \mathrm{s} \in \mathrm{S}\}$. A graph X is isomorphic to a Cayley graph on $G$ if and only if its auto orphism group $\operatorname{Aut}(\mathrm{X})$ has a subgroup isomorphic to G , acting regularly on vertices [1, Lemma 16.3].

A graph X is said to be vertex-transitive, edgetransitive or arc-transitive if $\operatorname{Aut}(\mathrm{X})$ acts transitively on $\mathrm{V}(\mathrm{X}), \mathrm{E}(\mathrm{X})$, or $\mathrm{A}(\mathrm{X})$, respectively. A graph is said to be half-arc-transitive provided that it is vertex-transitive and edge-transitive, but not arc-transitive. More generally, by a half-arc-transitive action of a subgroup G of $\operatorname{Aut}(X)$ on a graph $X$ we shall mean a vertextransitive and edge-transitive, but not arc-transitive action of $G$ on $X$. In this case, we shall say that the graph X is G-half-arc-transitive.

The investigation of half-arc-transitive graphs was initiated by Tutte[2] and he proved that a vertex- and edge-transitive graph with odd valency must be arctransitive. In 1970 Bouwer[3] constructed a 2 k -valent half-arc-transitive graph for every $\mathrm{k} \geq 2$ and later more such graphs were constructed. In fact, constructing and characterizing half-arc-transitive graphs with small valencies is currently an active topic in algebraic graph theory (see[4, 5]). It was shown in [6] gave the classification of tetravalent half-arc-transitive graphs of
order 2 pq . In this paper, we proved that hexavalent half-arc-transitive graph of order 6 p has order 42 .

## II. Preliminary Results

Now we state a simple observation about half-arctransitive graphs (see [7])

## A. Proposition 2.1

There are no half-arc-transitive graphs with fewer than 27 vertices.
The following proposition is straightforward (see [8, Propositions 2.1 and 2.2]).

## B. Proposition 2.2

Let $\mathrm{X}=\operatorname{Cay}(\mathrm{G}, \mathrm{S})$ be a half-arc-transitive graph. Then, there is no involution in $S$, and no $\alpha \in \operatorname{Aut}(G, S)$ such that $s^{\alpha}=s^{-1}$ for some $s \in S$. In particular, there are no half-arc-transitive Cayley graphs on abelian groups.
Li et al. [9] considered primitive half-arc-transitive graphs.

## C. Proposition 2.3

[9, Theorem 1.4] There are no vertex-primitive half-arctransitive graphs of valency less than 10 .
The following proposition can be extracted from Theorem 2.4 and Table 1 in [10].

## D. Proposition 2.4

Let X be a connected edge-transitive graph of order 2 p for a prime p .Then X is symmetric. Assume $\mathrm{p} \geqslant 7$. If X has valency 3 then one of the following holds:
(1) $\mathrm{X} \cong \mathrm{G}(2 \cdot 7,3)$ ), the Heawood graph of order 14 and $\operatorname{Aut}(\mathrm{G}(2 \cdot 7,3))=\operatorname{PGL}(2,7)$;
(2) $\mathrm{X} \cong \mathrm{G}(2 \mathrm{p}, 3), \mathrm{p} \geq 13$ and $3 \mid(\mathrm{p}-1)$. In this case, $\operatorname{Aut}(G(2 p, 3)) \cong\left(Z_{p} \times Z_{3}\right) \times Z_{2}$; If $X$ has valency 6 then one of the following holds:
(3) $\mathrm{X} \cong \mathrm{B}(\mathrm{PG}(2,5)), \quad \mathrm{p}=31$ and $\operatorname{Aut}(\mathrm{B}(\operatorname{PG}(2,5)))=$ РГL $(3,5) \times \mathrm{Z}_{2}$;
(4) $\mathrm{X} \cong \mathrm{B}^{\prime}(\mathrm{H}(11)), \mathrm{p}=11$ and $\operatorname{Aut}(\mathrm{B} 0(\mathrm{H}(11)))=$ $\operatorname{PSL}(2,11) \times \mathrm{Z}_{2}$;
(5) $\mathrm{X} \cong \mathrm{G}(2 \mathrm{p}, 6)$ and $6 \mid(\mathrm{p}-1)$. In this case, $\operatorname{Aut}(\mathrm{G}(2 \cdot 7,6))$
$\cong S_{7} \times Z_{2}$ and $\operatorname{Aut}(G(2 p, 6)) \cong\left(Z_{p} \times Z_{6}\right) \times Z_{2}$ for $p \geq 13$.
Now we give a well-known result.

## E. Proposition 2.5

Let X be a connected arc-transitive cubic graph of order 4 p , where p is a prime. Then X is one of the following: $\mathrm{Q}_{3}$, the 3-dimensional cube; $\mathrm{D}_{20}$, the dodecahedron; $\mathrm{C}_{28}$, the Coxeter graph; and $\operatorname{GP}(10,3)$, the generalized Peterson graph.
The following proposition can be extracted from [11] and [12].

## F. Proposition 2.6

Let X be a connected hexavalent edge-transitive graph of order $3 p$, where $p$ is a prime. If $X$ is half-arc-transitive, then $\mathrm{X} \cong \mathrm{M}(\mathrm{d} ;, 3, \mathrm{p})$ where $(\mathrm{d}, \mathrm{p}) \neq(2,7)$ or $(3,19)$ with $\mathrm{d} \mid(\mathrm{p}-1) / 3$. If X is symmetric then one of the following holds:
(1) $\mathrm{X} \cong T_{6}{ }^{C}$, the graph of order 30 and $\operatorname{Aut}\left(T_{6}{ }^{C}\right)=\mathrm{S}_{6}$;
$(2) \mathrm{X} \cong \mathrm{L}_{2}(19){ }_{57}^{6}, \mathrm{p}=19$ and with $\operatorname{Aut}(\mathrm{X}) \cong \operatorname{PSL}(2,19)$.
(3) $\mathrm{X} \cong \mathrm{G}(3 \mathrm{p}, 3)), 3 \mid \mathrm{p}-1$ and $\operatorname{Aut}(\mathrm{X})=\left(\mathrm{Z}_{\mathrm{p}}: \mathrm{Z}_{3}\right): \mathrm{S}_{3}$; (4) $\mathrm{X} \cong \mathrm{G}(\mathrm{p}, 2)\left[3 \mathrm{~K}_{1}\right]$.

Now we state two simple observations about half-arctransitive graphs.

## G. Proposition 2.7

[13, Proposition 2.6] Let $X$ be a connected half-arctransitive graph of valency 2 n . Let $\mathrm{A}=\operatorname{Aut}(\mathrm{X})$ and let $\mathrm{A}_{\mathrm{u}}$ be the stabilizer of $u \in V(X)$ in $A$. Then each prime divisor of $\left|A_{u}\right|$ is a divisor of $n!$. In particular, if $X$ has valency 6 then $A_{u}$ is a $\{2,3\}$-group.

## H. Lemma 2.8

Let $X$ be a connected edge-transitive graph of order 2 n and $A=\operatorname{Aut}(X)$. If $A$ has an abelian normal subgroup $N$ of order $n$, then X is a Cayley graph. Furthermore, If N is cyclic, and then X is non-half-arc-transitive.

## I. Proof

Suppose that N be an abelian normal sub group of A . Then X is bipartite graph with the two orbits of N as its two bipartite sets. It is easy to see that N acts regularly on each partite set of $X$. Thus, one may identify $R(N)=$ $\{R(n) \mid n \in N\}$ and $L(N)=\{L(n) \mid b \in N\}$ with the two partite sets of X . The actions of $\mathrm{n} \in \mathrm{N}$ on $\mathrm{R}(\mathrm{N})$ and on $\mathrm{L}(\mathrm{N})$ are just the right multiplication by n , that is $\mathrm{R}(\mathrm{g})^{\mathrm{n}}=\mathrm{R}(\mathrm{gn})$ and $\mathrm{L}(\mathrm{g})^{\mathrm{n}}=\mathrm{L}(\mathrm{gn})$ for any $\mathrm{g} \in \mathrm{N}$. Let $\mathrm{L}\left(\mathrm{n}_{1}\right)$, $\mathrm{L}\left(\mathrm{n}_{2}\right), \mathrm{L}\left(\mathrm{n}_{3}\right)$ and $\mathrm{L}\left(\mathrm{n}_{4}\right)$ be the vertices adjacent to $\mathrm{R}(1)$. Then $L\left(n_{1} n\right), L\left(n_{2} n\right), L\left(n_{3} n\right)$ and $L\left(n_{4} n\right)$ be the vertices adjacent to $R(n)$ for each $n \in N$. Since $N$ is abelian, $R\left(n_{1}^{-1} n\right), R\left(n_{2}^{-1} n\right), R\left(n_{3}^{-1} n\right)$ and $R\left(n_{4}^{-1} n\right)$ are the vertices adjacent to $L(n)$ for each $n \in N$. Define a map $\alpha$ by $\mathrm{R}(\mathrm{n}) \rightarrow \mathrm{L}\left(\mathrm{n}^{-1}\right)$ and $\mathrm{L}(\mathrm{N}) \rightarrow \mathrm{R}\left(\mathrm{n}^{-1}\right)$. It is easy to show that $\alpha \in \operatorname{Aut}(\mathrm{X})$. It follows that $\langle N, \alpha\rangle=2 \mathrm{n}$ and $\langle N, \alpha\rangle$ acts regularly on $\mathrm{V}(\mathrm{X})$. Thus, X is a Cayley graph. Furthermore, if N is cyclic, then $\langle N, \alpha\rangle=\mathrm{D}_{2 \mathrm{n}}$. We assume that $\mathrm{X}=\operatorname{Cay}\left(\mathrm{D}_{2 \mathrm{n}}, \mathrm{S}\right)$ and $\mathrm{D}_{2 \mathrm{n}}=<\mathrm{a}, \mathrm{b} \mid \mathrm{a}^{\mathrm{n}}=\mathrm{b}^{2}=1, \mathrm{a}^{\mathrm{b}}=$ $\mathrm{a}^{-1}>$. Note that $X$ is a bipartite graph. It follows that $S$ has no element of odd order. Thus, S contains involutions. By Proposition 2.2, X is not half-arctransitive.

Figure 1. Process flowchart of Theorem 3.1

## III. Main result

The following theorem is the main result of this paper. Fig . 1 showed the Proof flowchart of the theorem.

## A. Theorem 3.1

Let p be a prime and X be a hexavalent half-arctransitive graph of order6p. Then X has order 42.

## B. Proof

Suppose that X is a hexavalent half-arc-transitive graph of order $6 p$. Let $A=\operatorname{Aut}(X), u \in V(X)$ and denote by $A_{u}$
the stabilizer of $u$ in A. By Proposition 2.7, $\mathrm{A}_{\mathrm{u}}$ is a $\{2,3\}$-group and hence A is a $\{2,3, \mathrm{p}\}$-group with $|\mathrm{A}|$ not divisible by $\mathrm{p}^{2}$. The edge-transitivity of X implies that $18 \mathrm{p} \| \mathrm{A} \mid$. By Proposition 2.1, $\mathrm{p} \geq 5$, let N be a minimal normal subgroup and P a Sylow p -subgroup of A. Then $|\mathrm{P}|=\mathrm{p}$. Let B be abnormal subgroup of A. Let K be the kernel of A acting on the quotient graph $\mathrm{X}_{B}$ of X corresponding to the orbits of B. First we prove the following claims. Fig .2 showed peocess flowchart of the imprimitive part.

Figure2. process flowchart of the imprimitive

## C. Claim I

$B$ is not isomorphic to $Z_{6}, Z_{2 p}, Z_{3 p}$, Note that $|X|=6 \mathrm{p}$. By Lemma 2.8, $B$ is not isomorphic to $\mathrm{Z}_{3 \mathrm{p}}$. Let $\mathrm{C}=\mathrm{C}_{\mathrm{A}}(\mathrm{B})$. Suppose that $\mathrm{B}{ }^{\simeq} \mathrm{Z}_{6}$. Then $\mathrm{A} / \mathrm{C} \leq \mathrm{Z}_{2}$. Note that $\mathrm{p} \geq 5$. It follows that $\mathrm{P} \leq \mathrm{C}$. Then $\mathrm{BP} \cong \mathrm{Z}_{6 \mathrm{p}} \leq \mathrm{A}$ and BP acts regularly on $\mathrm{V}(\mathrm{X})$. It follows that X is a Cayley graph on group BP, by Proposition2.2, it is impossible. Suppose that $\mathrm{B}=\mathrm{Z}_{2 \mathrm{p}}$. Consider the quotient graph $\mathrm{X}_{B}$. Then $\left|\mathrm{X}_{\mathrm{B}}\right|=3$ and $X_{B}$ has valency 2, that is, $X_{B}$ is a 3-cycle, say $X_{B}=$ ( $B_{0}, B_{1}, B_{2}$ ) with $B_{i}$ and $B_{i+1}$ adjacent for each $i \in Z_{3}$. The induced subgraph $T=<B_{i}, B_{i+1}>$ of $B_{i} \cup B_{i+1}$ in $X$ is an edge-transitive cubic graph of order 4 p . Furthermore, T is bipartite. By Proposition 2.5, it is impossible.

## D. Claim II

If $B$ is $r$-group, then $B \xlongequal{\cong} Z_{r}$, where $r=2,3$ or $p$. If $B$ is p-group, then $B \cong Z_{p}$. Assume that $B$ is a 2 -group. Clearly, $B \leq K$ and since $|V(X)|=6 p$, orbits of $B$ on $V(X)$ are of length 2. Then, $\left|X_{B}\right|=3 p$ and $X_{B}$ has valency 2 or 6 . If $X_{B}$ has valency 2 then $X$ has at most valency 4 , a contradiction. Thus, $X_{B}$ has valency 6 . In this case, $K_{u}=$ $1, \mathrm{~K}=\mathrm{B} \xlongequal{\cong} \mathrm{Z}_{2}$. Now we assume that B is a 3-group. Then $\left|X_{B}\right|=2 p$ and $X_{B}$ has valency 2,3 or 6 . Suppose that $X_{B}$ has valency 2. Then $X \cong C_{2 p}\left[3 \mathrm{~K}_{1}\right]$ is symmetric, a contradiction. If $\mathrm{X}_{\mathrm{B}}$ has valency 3 , then $\mathrm{K}_{\mathrm{u}}$ fixes every out-neighbor of $u$ in the directed graph D , which implies $K_{u}=1$. Thus, $B=K=Z_{3}$. If $X_{B}$ has valency 6 then $K_{v}=1$ and $B=K=Z_{3}$.

## E. Claim III

A has a solvable minimal normal subgroup. Suppose that all minimal normal subgroups of A are no solvable. Then $\mathrm{N} \cong \mathrm{T}^{\mathrm{m}}$ where T is a nonabelian simple $\{2,3, \mathrm{p}\}$ group. Since $|\mathrm{A}|$ is not divisible by $\mathrm{p}^{2}$ and $\mathrm{p} \geq 5$, by $[14$, pp.12-14], we have that $\mathrm{m}=1$ and $\mathrm{N}=\mathrm{T}$ is isomorphic to $\mathrm{A}_{5}, \mathrm{~A}_{6}, \mathrm{~L}_{2}(7), \mathrm{L}_{2}(8), \mathrm{L}_{3}(3), \mathrm{U}_{3}(3), \mathrm{L}_{2}(17), \mathrm{U}_{4}(2)$. Let C $=\mathrm{C}_{\mathrm{A}}(\mathrm{N})$ and K be the kernel of N acting on the orbits of N . Since $\mathrm{C} \cap \mathrm{N}$ is a normal subgroup of N , then C is a $\{2,3\}$-group. Thus, C is solvable, it follows that $\mathrm{C}=1$. Then $\mathrm{A} \cong \mathrm{A} / \mathrm{C} \leq \operatorname{Aut}(\mathrm{N})$. Thus, N is not isomorphic to $\mathrm{A}_{5}$ or $\mathrm{L}_{2}(7)$ since $2 \cdot 3^{2} \cdot \mathrm{p} \| \mathrm{A} \mid$. Suppose that $\mathrm{N} \cong$ $\mathrm{L}_{2}(8)$. Then $\mathrm{A}=\mathrm{L}_{2}(8)$ or $\operatorname{Aut}\left(\mathrm{L}_{2}(8)\right)$, implying that $\left|\mathrm{N}_{\mathrm{v}}\right|=2^{2} \cdot 3$ or $2^{23} 3^{2}$. However, by Atlas, N has no subgroup of order $2^{2} \cdot 3$ or $2^{2} 3^{2}$, a contradiction. For the case $\mathrm{N} \cong \mathrm{U}_{3}(3)$ or $\mathrm{U}_{4}(2)$, we have the similarly contradiction. Suppose that $N \cong \operatorname{} \cong$ PSL $(2,17)$. Then $\mathrm{A}=$ $\operatorname{PSL}(2,17)$ or $\operatorname{PGL}(2,17)$. If $\mathrm{A}=\operatorname{PSL}(2,17)$, then $\left|\mathrm{A}_{\mathrm{v}}\right|=2^{3} \cdot 3$. Then $\mathrm{A}_{\mathrm{v}} \cong{ }^{\cong} \mathrm{S}_{4}$ is a maximal subgroup of A , it follows that A acts primitively on $\mathrm{V}(\mathrm{X})$. By Proposition 2.3 , it is impossible. If $A=\operatorname{PGL}(2,17)$, then $\left|A_{v}\right|=2^{4} \cdot 3$, which is impossible because A has no subgroup of order $2^{4} \cdot 3$.

Suppose $N \cong A_{6}$. Then $A \xlongequal{\cong} A_{6}$, or $\mathrm{A}_{6}<\mathrm{A} \leq \operatorname{Aut}\left(\mathrm{A}_{6}\right)$. Note that $3^{2}| | N \mid$. If $N$ is transitive, then $N$ is half-arctransitive. Thus, $\left|\mathrm{N}_{\mathrm{v}}\right|=12$ and $\mathrm{X} \xlongequal{\cong} \cos \left(\mathrm{A}_{6}, \mathrm{~N}_{\mathrm{v}}\left\{\mathrm{g}, \mathrm{g}^{-1}\right\} \mathrm{A}_{\mathrm{v}}\right)$ such that $\left|N_{v}\right| /\left|N_{v} \cap N^{g}\right|=3$ and $\left\langle N_{v}, g\right\rangle=A_{6}$ where $g \in$ $\mathrm{A}_{6}$. By Magma, it is impossible. Thus, N has two orbits, it follows that $\mathrm{N}_{\mathrm{v}} \cong \mathrm{S}_{4}<\mathrm{A}_{\mathrm{v}}$. Then N is primitive on each orbit since $\mathrm{S}_{4}$ is a maximal subgroup of N . By [15], the
length of the orbits of N on each orbit is $1,7,7$. It means that X cannot has valency 6 , a contradiction.

Suppose $N \xlongequal{\cong} L_{3}(3)$. Set $H=A_{v}$. Then $A=L_{3}(3)$ or $\operatorname{Aut}\left(\mathrm{L}_{3}(3)\right)$ and $\left|\mathrm{A}_{\mathrm{v}}\right|=2^{3} \cdot 3^{2}$ or $2^{4} \cdot 3^{2}$. Suppose that A $=\mathrm{L}_{3}(3)$. Then $\mathrm{X} \cong \cos \left(\mathrm{A}, \mathrm{H}\left\{\mathrm{g}, \mathrm{g}^{-1}\right\} \mathrm{H}\right)$ where $|\mathrm{H}|=72$ and $g \in L_{3}(3)$ such that $|H| /\left|H \cap H^{g}\right|=3$. It follows that $H \cap H^{g}$ is a subgroup of H with order 24 , which is impossible since H has no subgroup of order 24 . Now suppose that $\mathrm{A}=\mathrm{Aut}\left(\mathrm{L}_{3}(3)\right)$ and $\mathrm{X} \cong \cos \left(\mathrm{A}, \mathrm{H}\left\{\mathrm{g}, \mathrm{g}^{-1}\right\} \mathrm{H}\right)$ where $|\mathrm{H}|=2^{4} 3^{2}$ and $\mathrm{g} \in \mathrm{A} \backslash L_{3}(3)$ such that $|\mathrm{H}|\left|\mathrm{H} \cap \mathrm{H}^{\mathrm{g}}\right|=3$. By ATLAS, $A_{v}$ is a subgroup of $L_{3}(3)$. Thus, $H \cap H^{g}$ is a subgroup of H. By magma, it is impossible.

We have proved that A has at least one solvable minimal normal subgroup, say N. By Claim II, we have $\mathrm{N} \cong \mathrm{Z}_{\mathrm{p}}, \mathrm{Z}_{2}, \mathrm{Z}_{3}$. Let $\mathrm{C}=\mathrm{C}_{\mathrm{A}}(\mathrm{N})$. Suppose that $\mathrm{N} \cong \mathrm{Z}_{\mathrm{p}}$. Then $A / C \leq Z_{p-1}$. Suppose that $C=N$. Then $A$ is abelian, which is impossible. Thus, $\mathrm{C}>\mathrm{N}$. Let $\mathrm{M} / \mathrm{N}$ be a minimal normal subgroup of $\mathrm{A} / \mathrm{N}$ contained in $\mathrm{C} / \mathrm{N}$. Then M is a normal subgroup of A and $\mathrm{M} / \mathrm{N}$ is an elementary abelian r-group for $\mathrm{r}=2$ or 3 . Furthermore, $\mathrm{M}=\mathrm{N} \times \mathrm{R}$, where R is a Sylow r-subgroup of M . Clearly, R is characteristic in M and so normal in A. By Claim II, $\mathrm{R} \cong \mathrm{Z}_{2}$ or $\mathrm{Z}_{3}$. It follows that $M \xlongequal{\cong} Z_{2 p}$ or $Z_{3 p}$, contrary to Claim I Suppose that $\mathrm{N} \cong \mathrm{Z}_{2}$. By Claim II, we have $\mathrm{X}_{\mathrm{N}}$ has valency 6 , $\mathrm{K}_{\mathrm{u}}=1, \mathrm{~K}=\mathrm{N} \xlongequal{\cong} \mathrm{Z}_{2}$ and $\mathrm{A} / \mathrm{N} \leq \operatorname{Aut}\left(\mathrm{X}_{\mathrm{N}}\right)$. Then $\mathrm{X}_{\mathrm{N}}$ is $\mathrm{A} / \mathrm{N}$ -half-arc-transitive. Let $\mathrm{M} / \mathrm{N}$ be a minimal normal subgroup of $A / N$. Suppose that M/N is solvable. By Claim II, N is a maximal normal 2 -subgroup of A . Then $\mathrm{M} / \mathrm{N}$ is an elementary abelian r -group for $\mathrm{r}=3$ or p . Similarly, we have $\mathrm{M} \xlongequal{\cong} \mathrm{Z}_{6}$ or $\mathrm{Z}_{2 \mathrm{p}}$, contrary to Claim I. Thus, $\mathrm{M} / \mathrm{N}$ is unsolvable, it follows that $\mathrm{A} / \mathrm{N}$ is unsolvable. Note that $\mathrm{A} / \mathrm{N} \leq \operatorname{Aut}\left(\mathrm{X}_{\mathrm{N}}\right)$. By Proposition 2.6, $\mathrm{X}_{\mathrm{N}} \cong \mathrm{T}_{6}{ }^{\mathrm{C}}$ and $\mathrm{A}_{6} \leq \mathrm{A} / \mathrm{N} \leq \mathrm{S}_{6}$, or $\mathrm{X}_{\mathrm{N}} \cong \mathrm{L}_{2}(19)^{6}{ }_{57}$ and $\mathrm{A} / \mathrm{N}^{\cong} \mathrm{OSL}(2,19)$. For the latter case, $|\mathrm{A} / \mathrm{N}|=2^{2} \cdot 3^{2} \cdot 5 \cdot 19$, which is impossible because $A$ is a $\{2,3, p\}$ group. Thus, $\mathrm{A} / \mathrm{N} \cong{ }^{\cong} \mathrm{A}_{6}$ or $\mathrm{S}_{6}$, implying that $\mathrm{A} / \mathrm{N}$ is arc-transitive on $\mathrm{X}_{\mathrm{N}}$, a contradiction.
Suppose that $\mathrm{N} \cong_{Z_{3}}$. Then $\mathrm{A} / \mathrm{C} \leq \mathrm{Z}_{2}$. It follows that $\mathrm{p}||\mathrm{C}|$ and so $\mathrm{C}>\mathrm{N}$. Let $\mathrm{M} / \mathrm{N}$ be a minimal normal subgroup of $A / N$ contained in C/N. Suppose that M/N is solvable. By Claim II, N is a maximal normal 3subgroup of A . Then $\mathrm{M} / \mathrm{N}$ is an elementary abelian r group for $r=2$ or $p$. Similarly, we have $M \xlongequal{\cong} Z_{6}$ or $Z_{3 p}$, contrary to Claim I. Thus, $\mathrm{M} / \mathrm{N}$ is unsolvable, it follows that $\mathrm{A} / \mathrm{N}$ is unsolvable. By Claim II again, we have $\mathrm{X}_{\mathrm{N}}$ has valency 3 or $6, \mathrm{~K}_{\mathrm{u}}=1, \mathrm{~K}=\mathrm{N} \cong \mathrm{Z}_{3}$ and $\mathrm{A} / \mathrm{N} \leq \operatorname{Aut}\left(\mathrm{X}_{\mathrm{N}}\right)$. Suppose that $\mathrm{X}_{\mathrm{N}}$ has valency 6. Then $\mathrm{X}_{\mathrm{N}}$ is $\mathrm{A} / \mathrm{N}$-half-arctransitive. By Proposition 2.4, $\mathrm{X}_{\mathrm{N}} \cong \mathrm{B}^{\mathfrak{}}(\mathrm{H}(11))$ and $\operatorname{PSL}(2,11) \leq \mathrm{A} / \mathrm{N} \leq \operatorname{PSL}(2,11) \times \mathrm{Z}_{2}$, or $\mathrm{X}_{\mathrm{N}} \cong \mathrm{C}(\mathrm{PG}(2,5))$ and $\operatorname{PSL}(3,5) \leq \mathrm{A} / \mathrm{N} \leq \operatorname{P\Gamma L}(3,5) \times \mathrm{Z}_{2}, \mathrm{X}_{\mathrm{N}} \cong_{\mathrm{G}}(2 \cdot 7,6)$ and $\mathrm{L}_{2}(7) \times \mathrm{Z}_{2} \leq \mathrm{A} / \mathrm{N} \leq \mathrm{S}_{7} \times \mathrm{Z}_{2}$, or $\mathrm{X}_{\mathrm{N}} \cong_{\mathrm{O}_{3}}{ }^{\mathrm{C}}$ and $\mathrm{A}_{5} \leq \mathrm{A} / \mathrm{N} \leq \mathrm{S}_{5}$. For the first two cases, $|\operatorname{PSL}(2,11)|=2^{2} \cdot 3 \cdot 5 \cdot 11| | \mathrm{A} / \mathrm{N} \mid$ or $|\operatorname{PSL}(3,5)|=2^{5} \cdot 3 \cdot 5^{3} \cdot 31 \| \mathrm{A} / \mathrm{N} \mid$, which is impossible because $A$ is $\{2,3, p\}$-group. For the last two cases, $X_{N}$ is $\mathrm{A} / \mathrm{N}$-arc-transitive graph, a contradiction. Thus, $\mathrm{X}_{\mathrm{N}}$ has valency 3, then $\mathrm{X}_{\mathrm{N}} \cong \mathrm{O}_{3}$ and $\mathrm{A}_{5} \leq \mathrm{A} / \mathrm{N} \leq \mathrm{S}_{5}$, or $\mathrm{X}_{\mathrm{N}}$ is isomorphic to the Heawood graph and $\mathrm{A} / \mathrm{N} \cong \operatorname{PGL}(2,7)$. Then $\mathrm{M} \xlongequal{\cong} \mathrm{A}_{5} \times \mathrm{Z}_{3}$ or $\operatorname{PSL}(2,7) \times \mathrm{Z}_{3}$. Set $\mathrm{L}=\mathrm{A}_{5}$ or
$\operatorname{PSL}(2,7)$. Then L is a normal subgroup of A. Consider the quotient graph $X_{L}$. Then the length of the orbits of $L$ is $p$ or $2 p$ where $p=5$ or 7 . Furthermore, $\left|L_{v}\right|>1$, it follows that $X_{L}$ has valency 2.Then $X_{L}$ is a 3- or 6-cycle. Assume that the induced subgraph $T=<B_{i}, B_{i+1}>$ of $B_{i} \cup B_{i+1}$ where $B_{i}$ and $B_{i+1}$ are adjacent. Then $T$ is a cubic edgetransitive graph of order 2 p or 4 p . Furthermore, T is bipartite. By Proposition 2.4-2.5, we have T is isomorphic to Heawood graph and $\mathrm{p}=7$, that is X has order 42.

## IV. CONCLUSION

In the paper, we give the classification of hexavalent half-arc-transitive graphs of order 6 p . It is proved that the graph must have order 42 if hexavalent half-arc transitive graph of order $6 p$ is available. In addition, from the proof we know that the quotient graph is a well-known graph-Heawood graph. However, we should further verify whether the graph belongs to half-arc transitive graph or not. In addition, we [6] proved that if tetravalent half-arc-transitive graphs of order 2pq exist, then $p-1$ is divisible by $2 q$. In another paper[13], we showed that hexavalent half-arc-transitive graphs of order 4 p exist if and only if $\mathrm{p}-1$ is divisible by 12 . Therefore, we guess that hexavalent half-arc-transitive graphs of order 2 pq exist if and only if $\mathrm{p}-1$ is divisible by 3 q , where q is a prime number no less than 5 . In next paper, we wish to determine whether the 42 -point half-arc-transitive graph exists or not.. In addition, we hope to classify the hexavalent half-arc-transitive graphs of order 2 pq .
