Abstract

This work proposes a two-stage immune algorithm that embeds the compromise programming to perform multi-objective optimal capacitor placement. A new problem formulation model that involves fuzzy sets to reflect the imprecise nature of objectives and incorporates multiple planning requirements is presented. The proposed approach finds a set of non-inferior (Pareto) solutions rather than any single aggregated optimal solution. Additionally, this developed approach eliminates the need for any user-defined weight factor to aggregate all objectives. Comparative studies are conducted on an actual system with encouraging results, demonstrating the effectiveness of the proposed presented approach.

Keywords: Fuzzy modeling, Capacitor placement, immune algorithm, non-inferior set, compromise programming.

1. INTRODUCTION

Typical distribution systems operate in a radial configuration; they are supplied from substations and feed to distribution transformers. The spatial density of the load is high in urban areas, where underground cables and large transformers are used, but lower in mixed and rural areas, where overhead lines and smaller transformer units are used. Numerous shunt capacitors are installed along distribution feeders to compensate for reactive power to regulate the voltage; reduce energy; correct the power factor, and release system capacity, for both urban and rural areas. The general capacitor placement problem is to locate and determine the sizes of capacitors to be installed at the nodes of a radial distribution system under various loading conditions.

Various attempts from different perspectives have been made to solve the capacitor placement problem. For instance, the problem has been formulated as a

mixed integer programming problem in which power flows and voltage constraints are applied [1]. Optimal capacitor planning has been implemented based on the fuzzy algorithm in practical distribution systems [2]. A solution technique based on simulated annealing (SA) has been developed; implemented in a software package, and tested on a real distribution system with 69 buses [3,4]. The Tabu Search technique has been applied to determine the optimal capacitor planning in the distribution system used in [5], and the results of the TS compared with those of the SA. Genetic algorithms (GA) have been used to determine the optimal selection of capacitors [6].

Notably, most of these approaches treat the capacitor placement problem as a single objective problem. However, in recent years, customers have made strong demands of electrical utility companies [7]. Various problems have multiple and conflicting objectives, which make the optimization problem interesting to solve. No single solution is an optimal solution to a problem with multiple conflicting objectives, so a multi-objective optimization problem has a number of trade-off optimal solutions. Classical optimization methods can at best find one solution in one simulation run, so such methods inconvenient when used to solve multi-objective optimization problems.

In light of the above, this study formulates the capacitor placement problem as a multiple objective problem, including operational requirements. This work also presents a two-staged immune algorithm to solve the constrained multiple objective problem.

2. Problem Formulation

This study formulates the capacitor allocation problem to determine the locations and size of capacitors to be installed in the nodes of a radial distribution system under various loading conditions. The problem formulation considers four objective functions, to minimize the total cost of capacitors to be installed,

the energy loss and the deviation of bus voltage, and to maximize the system security margin of transformer capacity.

2.1. Minimizing capacitor construction expenditure

The cost of capacitors includes the purchase cost and installment and maintenance cost.

$$\min f_c = \sum_{i \in \Psi} \frac{1}{y} [k_p(q) + k_m(q)] a_i \quad (1)$$

where a_i is a 0-1 decision variable: $a_i = 1$ if the i th bus is selected for capacitor installation; otherwise $a_i = 0$; Ψ represents the set of candidate locations of buses to be considered for capacitor injection; y denotes the life time (years) of the capacitors; k_p represents the purchased cost of capacitors of capacitance q ; k_m denotes the fixed installment and maintenance cost. Figure 1 plots the fuzzy membership function f_c of the cost.

2.2. Minimizing real power loss

The total cost of the real power loss from line branches, is defined as,

$$\min f_e = \sum_{j=1}^{n_l} k_{ej} t_j p_{loss,j} \quad (2)$$

where n_l represents the total number of load levels; k_{ej} represents the cost of power under load j ; t_j represents the duration of the application of load j , and $p_{loss,j}$ is the total real power loss of the considered system under load j . Figure 2 displays the fuzzy membership function of power loss.

2.3. Minimizing Deviation of Bus Voltage

An index is defined that quantifies the deficiency in the system caused by the bus voltage.

$$\min f_v = \max_i |v_i - v_i^{Rated}|, i=1, 2, 3, \dots, n_b \quad (3)$$

where n_b is the total number of buses; v_i and v_i^{Rated} denote the real and rated voltages of bus i , respectively, and f_v represents the maximal deviation of the bus voltage in the system. A lower f_v corresponds to a higher quality voltage profile and better system security. Figure 3 plots the fuzzy membership function of the deviation of the bus voltage where f_{vmax} is the maximum allowable deviation of bus voltage.

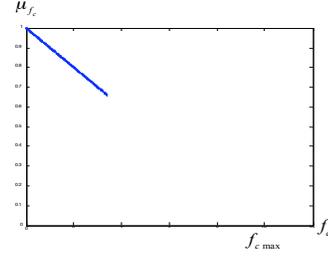

Fig. 1. Fuzzy membership function of the cost, f_c

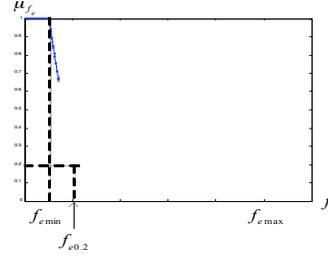

Fig. 2. Fuzzy membership function of power loss

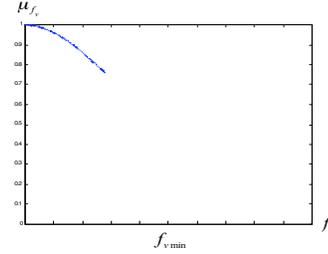

Fig. 3. Fuzzy membership function of the deviation of the bus voltage

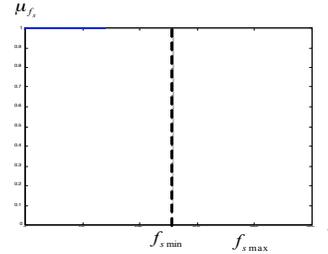

Fig. 4. Fuzzy membership function of the security margin of feeders and transformers

2.4. Maximizing the Security Margin of Feeders and Transformers

A simple index to assess the system security is the capacity margin of feeders and transformers.

$$\min f_s = 1 - \min_i \left| \frac{I_{iRate}^2 - I_{iLoad}^2}{I_{iRate}^2} \right|, i = 1, 2, \dots, n_h \quad (4)$$

where I_{iLoad} and I_{iRetad} are the current flow and the rate

flow of branch (transformer) i , respectively; n_h represents the total number of branches (transformers), and f_s denotes the security and system capacity index of the feeders. Lower f_s implies more secure system capacity. Figure 4 plots the fuzzy membership function of the feeders (transformers).

3. Immune Algorithm

The immune system has a fundamental ability to produce new types of antibody or find the best-fitting antibody to attack an invading antigen [8, 9]. The immune system produces very many antibodies against innumerable, unknown antigen, by trial and error. The diversity of the immune system can be mathematically formulated as a multi-objective function optimization problem, with multiple solutions rather than single solution, to elucidate the diversity of antibodies that is essential to adaptability against foreign viruses and bacteria in the environment. A measure of diversity of antibodies produced from a lymphocyte population is required and must be defined. According to information theory, the entropy $H_j(N)$ of the j th gene is defined as [8,9]

$$H_j(N) = -\sum_{i=1}^N p_{i,j} \log p_{i,j} \quad (5)$$

where $p_{i,j}$ represents the probability that locus j is allele i . If all alleles at the j th gene are the same, then the entropy of the j th gene equals zero. The mean of the informative entropy in a lymphocyte population is represented by

$$H(N) = \frac{1}{L} \sum_{j=1}^L H_j(N) \quad (6)$$

where $H(N)$ denotes the mean of the informative entropy for all antibodies and L is the size of the genes in an antibody. This entropy specifies the diversity of the lymphocyte population. Two expressions for affinity are considered in the presented approach. One $(Ab)_{vw}$, is used to determine the diversity between two antibody v and w and can be represented as,

$$(Ab)_{vw} = \frac{1}{1 + H(2)} \quad (7)$$

where $H(2)$ quantifies the diversity between two antibodies, according to Eq. (7) for $N=2$. For $H(2) = 0$, the genes of the two antibodies are identical. The other affinity $(Ag)_i$ is that between antigen A_g and antibody A_b and is defined by

$$(Ag)_i = \mu_{f_i}(A_{bi}) - \sum_{j=1}^{N_c} \mu_{g_j}(A_{bi}) \quad i = 1, 2, \dots, N_o \quad (8)$$

where $\mu_{f_i}(A_{bi})$ is the value of the membership function for antibody A_{bi} on objective i ; $\sum_{j=1}^{N_c} \mu_{g_j}(A_{bi})$

are the values of the membership function with all applied constraints for antibody A_{bi} , and N_c and N_o are the numbers of constraints and objectives, respectively. The antibody is perfectly matched with the antigen when the affinity $(Ag)_i$ equals one. Antibodies that have high affinities toward an antigen are selected to proliferate, while antibodies with low concentrations are suppressed. The concentration c_v of each antibody can be defined as

$$c_v = \frac{1}{N_o} \sum_{w=1}^{N_o} ac_{v,w} \quad (9)$$

and

$$ac_{v,w} = \begin{cases} 1 & (Ag)_i \geq \varepsilon \\ 0 & \text{otherwise} \end{cases} \quad (10)$$

where ε is a preset threshold. If c_v ($v = 1, 2, \dots, N_o$) is greater than a given threshold δ_c , then this antibody becomes a memory antibody; else, it is suppressed. The goal of this step is to eliminate surplus solution candidates.

From the schema of the natural immune system, the mathematical optimization framework can be modeled as an algorithm, realized by the following steps.

Notably, in the above immune algorithm, the number of generated antibodies and the number of iterations can be experimentally determined. The rate of the crossover and mutation are also determined on a trial basis.

This study presents a two-stage immune algorithm embedded the compromise program to solve multi-objective problems.

In the first stage, the multi-objective optimization problem is transformed to a single objective optimization problem by selecting the k th objective as the primary objective function in turns $k = 1, 2, \dots, N_o$ and converting the other objectives to constraints with individual maximum allowable values \tilde{f}_i where $i = 1, 2, \dots, N_o$ and $i \neq k$.

In the second stage, the non-inferior set for all objectives is obtained by compromise programming. Compromise programming finds the best compromise with respect to all the objectives by computing a normalized Euclidean distance measure.

$$D = \sum_{i=1}^{N_o} \frac{f_i(x) - \tilde{f}_i}{\tilde{f}_i - \tilde{f}_i} \quad (11)$$

This normalized Euclidean distance is used to evaluate how close the computed non-inferior solution is to the Pareto front. A smaller D indicates the current computed non-inferior solution is closer to the Pareto front. For a multi-objective problem, the ideal value of each objective f_i (from stage 1) and the maximum allowable value of each individual objective \tilde{f}_k where i and $k = 1, 2, \dots, N_o$, can be used to express the overall

multi-objective minimizing objective function, as follows.

$$\text{Min } D = \sum_{i=1}^{N_o} \frac{f_i(x) - \tilde{f}_i}{\tilde{f}_i - \tilde{f}_i} \quad (12)$$

4. Simulation Results

The testing system includes seven branches and 69 buses, as presented in [3]. The presented method outputs five non-inferior solutions (options) with different features, one of which is to be selected by the decision-makers. Tables 1 and 2 compare the results with those in [3] and [10], in terms of the capacitor to be installed and power loss with and without compensation, respectively. In summary, the non-inferior solutions obtained using the presented method, in terms of voltage deviation, power loss, cost and loading margin, are better than (or similar to) those obtained using the methods of [3] and [10].

TABLE I
CAPACITORS(kvar) TO BE INSTALLED

No. of bus	Methods						
	The proposed method					Huang	Chiang
19	300	1200	300	600	300	600	300
50	300	900	600	900	300	300	1200
53	1200	600	600	600	600	300	0
Total_kvar	1800	2700	1500	2100	1200	1200	1500

TABLE II
THE RESULT OF THE REAL POWER LOSS (kw) WITH AND WITHOUT INSTALLING CAPACITORS

Load level	Without compensation	With compensation						
		The proposed method					Huang	Chiang
Light	538	393	457	347	401	337	347	345

Peak	3,190	1,865	1,752	1,965	1,806	2,134	2,276	1,964
Total_loss	5,443	3,277	3,204	3,354	3,201	3,587	3,809	3,349

5. Conclusions

Multi-objective optimization is of increasing importance in various fields, and has a diverse range of applications. Highly effective and efficient multi-objective algorithms can promote both scientific research and engineering applications in various areas. This work proposes the two-stage immune algorithm, embedding compromise programming, for solving the multi-objective capacitor placement problem. The

concept of the non-inferior set is applied herein to obtain the set of optimal compromise solutions from which the decision maker can choose one. The simulation results indicate that the advantage of using the proposed technique is that it can find the best compromised solutions in a single run.
